PRELIMINARY RESULTS OF ALTITUDE-WIND-TUNNEL INVESTIGATION

OF X24C-4B TURBOJET ENGINE

V - PERFORMANCE OF MODIFIED ENGINE

By William R. Prince, and Harry E. Bloomer

SUMMARY

An investigation has been conducted in the NACA Cleveland altitude wind tunnel to evaluate the performance characteristics of a modified X24C-4B turbojet engine over a range of simulated altitudes from 5000 to 45,000 feet, simulated flight Mach numbers from 0.25 to 1.07, and engine speeds from 4000 to 12,500 rpm. The engine was modified by the manufacturer to improve the velocity and temperature profiles within the engine. Performance data are graphically presented to show the effect of altitude at a flight Mach number of 0.25 and the effect of flight Mach number at an altitude of 25,000 feet. Original and modified engine performances for several specific operating conditions are compared. A complete tabulation of average pressures and temperatures throughout the engine, performance data, and lubrication and fuel-system data is presented.

The average temperature pattern at the turbine outlet for the modified engine conformed more closely to the manufacturer's desired temperature distribution than for the original configuration. A comparison of original and modified engine performance data showed that with the modified configuration a thrust increase from 5 to 14 percent based on original engine output was obtained for several specific operating conditions. Application of the generalization factors showed that performance variables depending upon fuel consumption that are obtained at one altitude cannot be used in predicting the values of these parameters at any other altitude; however, thrust and air-flow values can be predicted for a limited range of altitudes from data taken at one altitude.

INTRODUCTION

Performance and operational characteristics of an X24C-4B turbojet engine have been investigated in the NACA Cleveland altitude wind tunnel at the request of the Bureau of Aeronautics, Navy Department. Data presenting pressure and temperature distributions, engine performance, and compressor performance are reported in references 1, 2, and 3, respectively.

A modified X24C-4B turbojet engine was investigated after completion of the tests of the original engine. Engine modifications were made by the manufacturer to improve the velocity and temperature profiles within the engine. The effect of the modifications on the compressor performance is presented in reference 4.

The effects of altitude and flight Mach number on the performance of the modified engine are presented herein. The applicability of methods used to generalize the data in order to estimate the performance at various altitudes from performance data obtained at any altitude is discussed. A complete tabulation of average pressures and temperatures throughout the engine, performance data, and lubrication and fuel-system data is presented.

APPARATUS AND INSTRUMENTATION

The modified engine was installed in a wing nacelle in the test section of the altitude wind tunnel in the same manner as the original engine (fig. 1). In order to obtain pressures at the engine inlet that corresponded to a wide range of flight Mach numbers, dry refrigerated air was supplied to the engine through a duct from the tunnel make-up air system. The compressor, the combustion chamber, and the exhaust nozzle of the basic X24C-4B engine, described in detail in reference 1, were modified for the present investigation.

The compressor was modified to improve the radial velocity distribution at the compressor-outlet annulus by twisting the eleventh-stage rotor blade tips 6° in the direction of reduced angle of attack.

The combustion chamber (fig. 2) was modified to improve the temperature distribution at the turbine inlet. The wall perforations of the fourth step of the combustion-chamber liner were omitted and the circular wall perforations in the third step were changed to rectangular. The total area of the holes in the third step of the modified liner was equal to the hole area of the third

and fourth steps in the original liner. Introducing the air into the combustion chamber farther upstream, and thereby increasing the penetration, improved the mixing in the secondary combustion zone. The blocking area of the screens at the annular combustion-chamber inlet was reduced. For the original configuration, a screen having 60-percent blocking area was installed in the outer annulus and one having 40-percent blocking area was installed in the intermediate annulus. In the modified combustion chamber, these screens were replaced by two screens of 30-percent blocking area. The fuel nozzles for the modified engine had a rated capacity of 7 gallons per hour at a differential pressure of 100 pounds per square inch, as compared to $7\frac{1}{2}$ gallons per hour for the original engine.

With improved temperature distribution at the turbine inlet, the manufacturer increased the allowable temperature limits at the turbine outlet from 1250° to 1400° F, as indicated by the hottest thermocouple; a reduction in exhaust-nozzle area was consequently required to obtain the new temperature limits with the modified engine. The exhaust nozzle used in this investigation had an outlet area of 170.6 square inches as compared to an area of 183.1 square inches for the original engine.

Temperature and pressure measurements were obtained at eight stations in the engine (fig. 3). The instrumentation installed in the modified engine remained the same as that in the original configuration with the exception of the addition of three temperature rakes at the turbine outlet, making a total of 55 thermocouples at that survey station. Location and details of the instrumentation installed in the original engine are presented in reference 1.

PROCEDURE

Performance characteristics of the engine were obtained at simulated altitudes from 5000 to 45,000 feet, simulated flight Mach numbers from 0.09 to 1.07, and engine speeds from the idling speed of 4000 rpm to the rated speed of 12,500 rpm. For most operating conditions, the inlet-air temperature was held at approximately NACA standard values corresponding to the simulated flight conditions. Inlet-air temperatures below -20° F, corresponding to high altitude and low flight Mach number, were not obtained. At the higher altitudes, the minimum engine speed was sometimes limited by combustion blowout and the maximum engine speed by a turbine-outlet temperature of 1400° F at the hottest thermocouple.

Thrust was measured with the tunnel balance scales and was also calculated from pressure and temperature measurements obtained at the exhaust-nozzle outlet. Air flow was calculated from pressure and temperature measurements made in the engine-inlet duct and at the exhaust-nozzle outlet. Both values of jet thrust and air flow are presented in the tabulated data; performance parameters presented in the tabulated data and the performance curves that involve thrust and air flow are calculated by using thrust measured by the balance scales and air flow measured at the engine inlet. The methods of calculation used in this report are the same as presented in reference 2.

RESULTS AND DISCUSSION

A summary of performance data, average pressures and temperatures throughout the engine, and lubrication and fuel-system data is presented in tables I, II, and III, respectively, for all altitudes, flight Mach numbers, and engine speeds at which data were obtained with the modified engine and a 170.6-square-inch exhaust nozzle. A comparison of average temperature patterns at the turbine outlet for both the original and modified engines showing the relation to the manufacturer's desired temperature distribution is presented in figure 4 for an altitude of 5000 feet, engine speed of 12,500 rpm, and a flight Mach number of 0.25. In order to conserve turbine life, operation of the original engine was limited to a maximum turbine-outlet temperature limit of 1250° F (1710° R). As a result of the modifications made to the engine, the temperature distribution at the turbine inlet was improved and the temperature limit raised to 1400° F (1860° R) as indicated by the hottest thermocouple. The average temperature pattern at the turbine outlet for the modified engine with a 1400° F limit (fig. 4) conformed more closely to the manufacturer's desired temperature distribution than did the original configuration. The data indicate that the temperature limit for the original engine was somewhat conservative than that of the modified engine.

Engine Performance

Effect of altitude. - The effect of altitude on engine performance is shown in figure 5 for data obtained at a constant flight Mach number of 0.25 and altitudes from 5000 to 45,000 feet. The trends of the performance curves for the modified engine followed closely those of the original engine. Jet thrust, net thrust, air flow, and fuel consumption are presented in figures 5(a), 5(b), 5(c), and 5(d), respectively.

The specific fuel consumption based on net thrust (fig. 5(e)) was not appreciably affected at any engine speed when the altitude was raised from 5000 to 15,000 feet and was unaffected at engine speeds above 10,000 rpm when the altitude was raised to 25,000 feet; however, further increase in altitude above 25,000 feet raised the specific fuel consumption at all engine speeds.

The fuel-air ratio (fig. 5(f)) increased as the altitude was raised; the increase in fuel-air ratio became more pronounced at the high altitudes. The minimum fuel-air ratio occurred at an engine speed between 9000 and 10,000 rpm for each altitude.

The exhaust-nozzle-outlet total temperature (fig. 5(g)) increased at the high engine speeds as the altitude was raised. For engine speeds below approximately 11,000 rpm, an increase in altitude to 25,000 feet decreased the exhaust-nozzle-outlet temperature; however, for altitudes above 25,000 feet, the temperature increased considerably.

Effect of flight Mach number. - The effect of flight Mach number on engine performance is shown in figure 6 for data obtained at an altitude of 25,000 feet and flight Mach numbers from 0.25 to 1.07. For all engine speeds, raising the flight Mach number increased the jet thrust (fig. 6(a)), air flow (fig. 6(c)), and specific fuel consumption based on net thrust (fig. 6(e)).

Raising the flight Mach number from 0.25 to 0.53 decreased net thrust (fig. 6(b)) throughout the entire range of engine speeds presented. As flight Mach number was increased beyond 0.53, net thrust decreased at low engine speeds and increased at high engine speeds.

As the flight Mach number was raised, the fuel consumption (fig. 6(d)) increased at engine speeds above 10,000 rpm and decreased at lower engine speeds. The fuel-air ratio (fig. 6(f)) decreased at all engine speeds as the flight Mach number was raised from 0.25 to 0.86 but increased at high engine speeds with a further increase in flight Mach number.

Throughout the range of engine speeds, the exhaust-nozzle-outlet temperature (fig. 6(g)) decreased for flight Mach numbers up to and including 0.86 but increased slightly at high engine speeds with a further increase in flight Mach number.

Generalized Performance

The altitude performance data that were presented in figures 5 and 6 have been generalized to standard sea-level conditions by use of the factors 8, ratio of absolute ambient static pressure to absolute static pressure corresponding to NACA standard atmosphere at sea level, and 9, ratio of absolute ambient static temperature to absolute static temperature corresponding to NACA standard atmosphere at sea level. The generalized performance data are presented in figures 7 and 8. The concept of flow similarity and the application of dimensional analysis to the performance of turbojet engines has led to the development of these factors with which data obtained at several altitudes may be generalized. In the development of this method of generalization, the efficiencies of the engine components were considered to be unaffected by changes in altitude.

Effect of altitude. - The effect of altitude on generalized engine performance is shown in figure 7 for data obtained at a constant flight Mach number of 0.25 and altitudes from 5000 to 45,000 feet.

Jet thrust, net thrust, and air flow were the only performance data that generalized to a single curve at any engine speed or altitude for which data were obtained. Application of the generalization factors corrected the jet thrust (fig. 7(a)) and net thrust (fig. 7(b)) to a single curve at altitudes up to 15,000 feet for all engine speeds. At corrected engine speeds below 10,500 rpm, the jet thrust and net thrust generalized to a single curve at altitudes up to 25,000 feet. For all engine speeds, the corrected jet thrust and corrected net thrust increased as the altitude was raised above 25,000 feet. The air flow (fig. 7(c)) generalized to a single curve at altitudes up to 25,000 feet for all engine speeds; increase in altitude above 25,000 feet decreased the corrected air flow at all engine speeds.

Corrected fuel consumption (fig. 7(d)), corrected specific fuel consumption based on net thrust (fig. 7(e)), corrected fuel-air ratio (fig. 7(f)), and corrected exhaust-nozzle-outlet total temperature (fig. 7(g)) increased markedly as the altitude was raised.

Failure of the thrust and air-flow data to generalize for all altitudes and corrected engine speeds is attributed to the change in compressor efficiency with altitude. Failure of variables depending upon fuel consumption (figs. 7(d) to 7(g)) to generalize

to a single curve for any engine speed or altitude at which data were obtained is attributed to changes in compressor and combustion efficiency with altitude.

Effect of flight Mach number. - The effect of flight Mach number on engine performance generalized to standard sea-level conditions is shown in figure 8 for data obtained at an altitude of 25,000 feet and at flight Mach numbers from 0.25 to 1.07. The effect of flight Mach number on the generalized performance was similar to the effect on the engine performance data presented in figure 5. The data presented in figure 8 do not represent the absolute generalized sea-level performance of the engine inasmuch as the application of the generalization factors did not correct the performance data for various altitudes to a single curve.

Comparison of original and modified engine performance. - Data showing the percentage change in the corrected values of net thrust and specific fuel consumption based on net thrust for the modified engine as compared to the original engine for several specific operating conditions are presented in the following table:

(a) Corrected engine speed, 13,000 rpm^a; altitude, 25,000 feet.

Flight Mach number	Corrected net thrust (lb)		Change in corrected net thrust (percent)	Corrected specific fuel consumption based on net thrust, (lb)/(hr)(lb thrust)		Change in corrected specific fuel con- sumption based on net thrust (percent)
	Orig- inal engine	Modi- fied engine		Original engine	Modified engine	
0.25	2925	3150	.8	1.250	1.225	-2
.53	2760	3040	10	1.370	1.355	-1
.73	2760	3040	10	1.400	1.400	0
.86	2925	3210	10	1.445	1.445	0
1.07	3050	3490	14	1.510	1.560	3

^aEngine speeds are the maximum speeds at which data were obtained over the complete range of test conditions.

(b) Corrected engine speed, 12,000 rpm^a; flight Mach number, 0.25.

Altitude (ft)	Corrected net thrust (lb)		Change in corrected net thrust (percent)	Corrected specific fuel consumption based on net thrust, (lb)/(hr)(lb thrust)		Change in corrected specific fuel con- sumption based on net thrust (percent)
	Orig- inal engine	Modi- fied engine		Original engine	Modified engine	
5,000	2200	2320	5	1.175	1.165	-1
15,000	2200	2320	5	1.220	1.200	-2
25,000	2200	2400	9	1.280	1.230	-4
35,000	2340	2480	6	1.365	1.365	0
45,000	2525	2810	11	1.540	1.490	-3

^aEngine speeds are the maximum speeds at which data were obtained over the complete range of test conditions.

SUMMARY OF RESULTS

The following results were obtained from the altitude-wind-tunnel investigation of the modified X24C-4B turbojet engine at simulated altitudes from 5000 to 45,000 feet, simulated flight Mach numbers from 0.25 to 1.07, and engine speeds from 4000 to 12,500 rpm:

1. The average temperature pattern at the turbine outlet for the modified engine conformed more closely to the manufacturer's desired temperature distribution than did the original configuration.
2. A comparison of original and modified engine performance data showed that with the modified configuration a thrust increase of from 5 to 14 percent based on original engine output was obtained for several specific operating conditions.
3. Application of the generalization factors showed that performance variables depending upon fuel consumption that are obtained at one altitude cannot be used in predicting the values of these variables at any other altitude; however, thrust and air-flow values can be predicted for a limited range of altitudes from data taken at one altitude.

4. The specific fuel consumption based on net thrust increased at all engine speeds at a flight Mach number of 0.25 when the altitude was raised above 25,000 feet. Increasing the flight Mach number raised the specific fuel consumption based on net thrust at all engine speeds.

^aData not obtained for pump-inlet and pump-outlet pressures because engine governor was not installed.^bData not obtained.

NACA RM NO. SE7L22b

CONT'D ON BACK

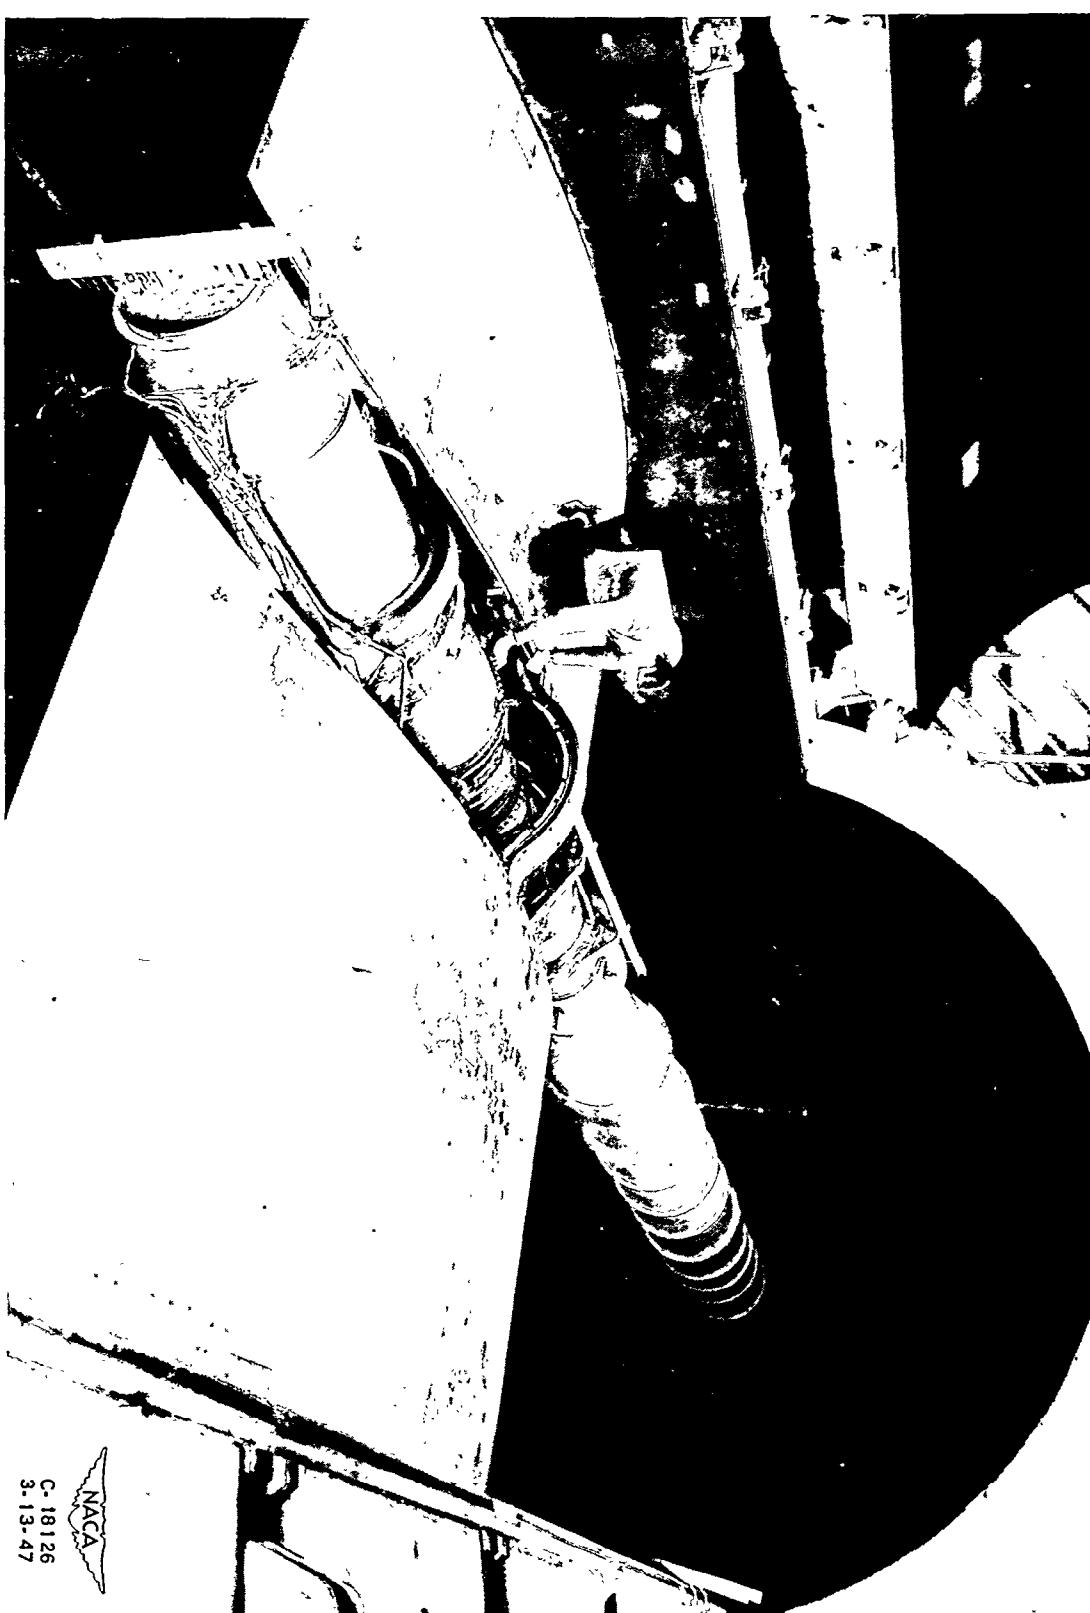

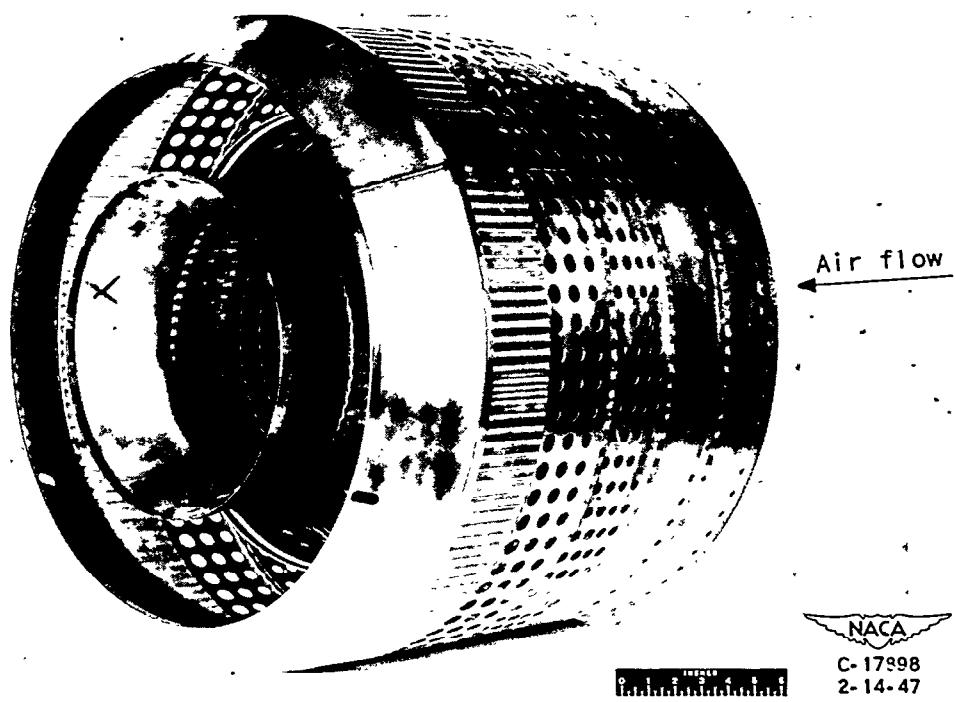

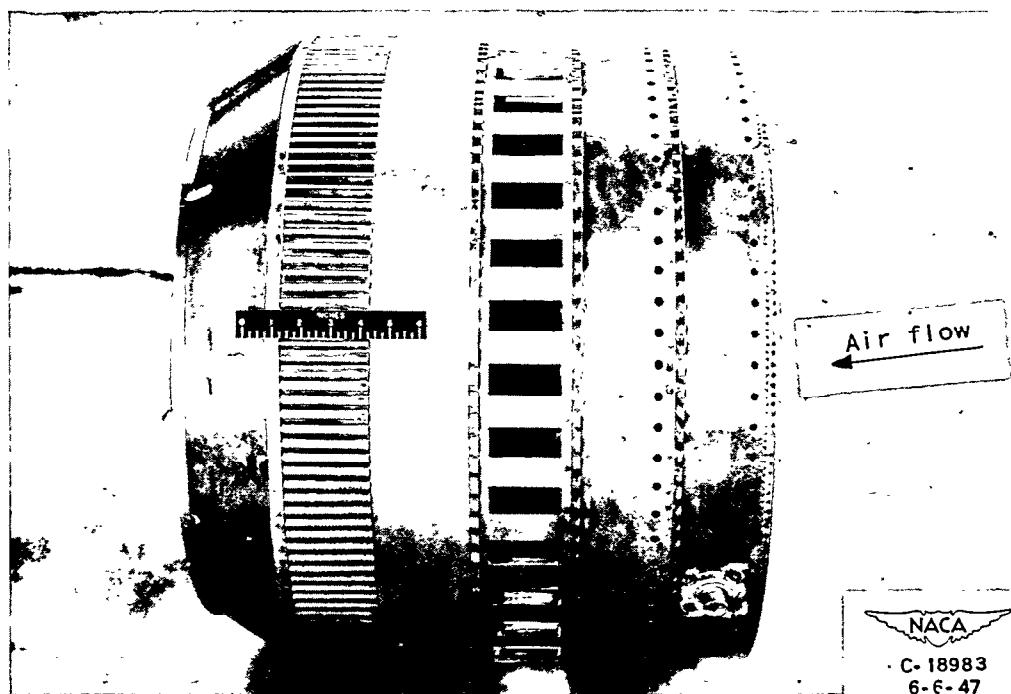

Figure 1. - Installation of X-24C-4B turbojet engine in altitude wind tunnel.

(a) Original configuration.

(b) Modified configuration.

Figure 2. - Comparison of original and modified combustion chambers.

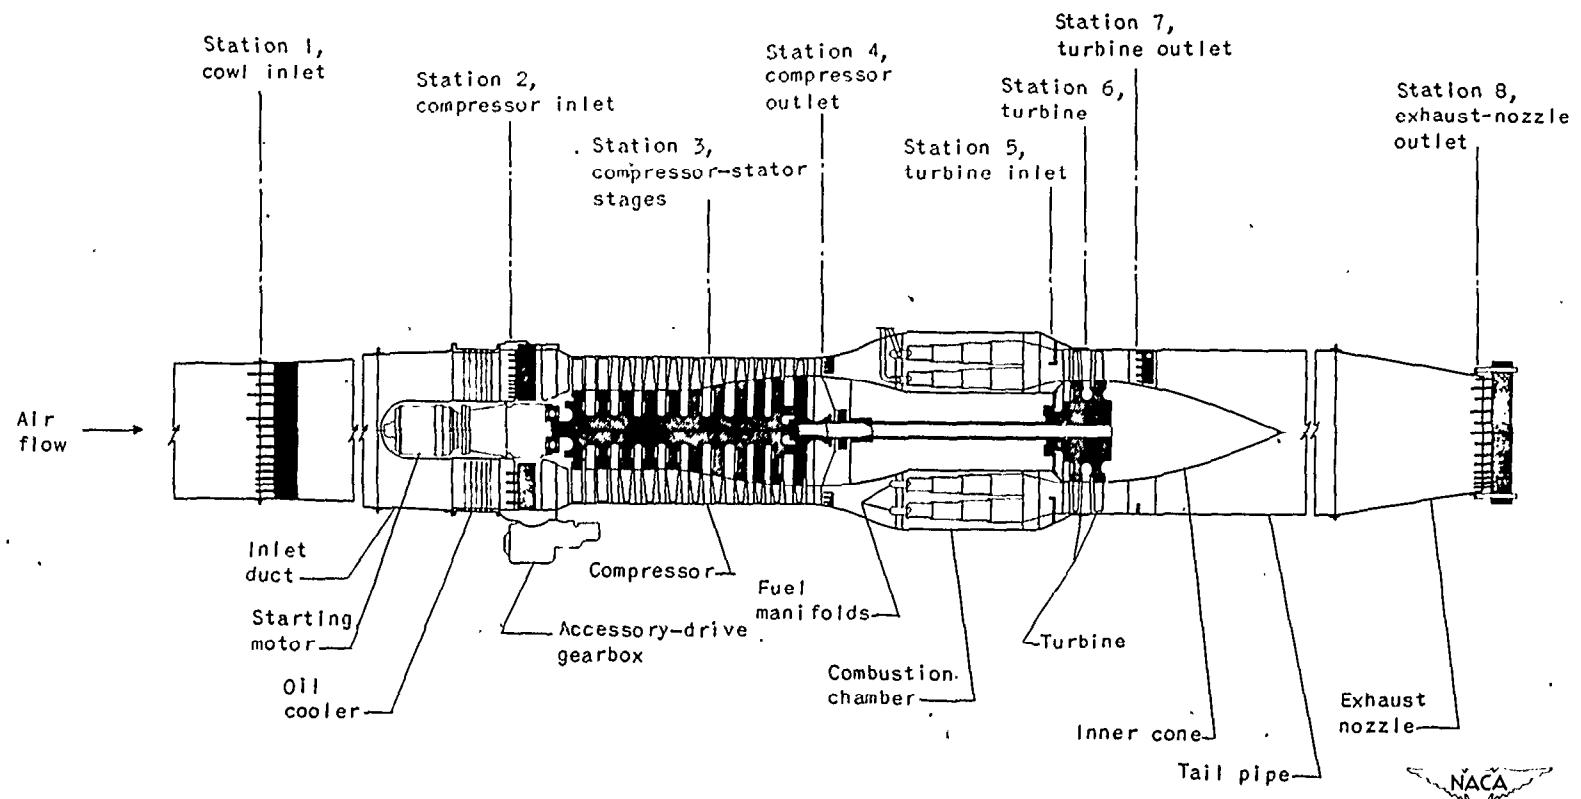

Figure 3. - Location of instrumentation installed in X24C-4B turbojet engine.

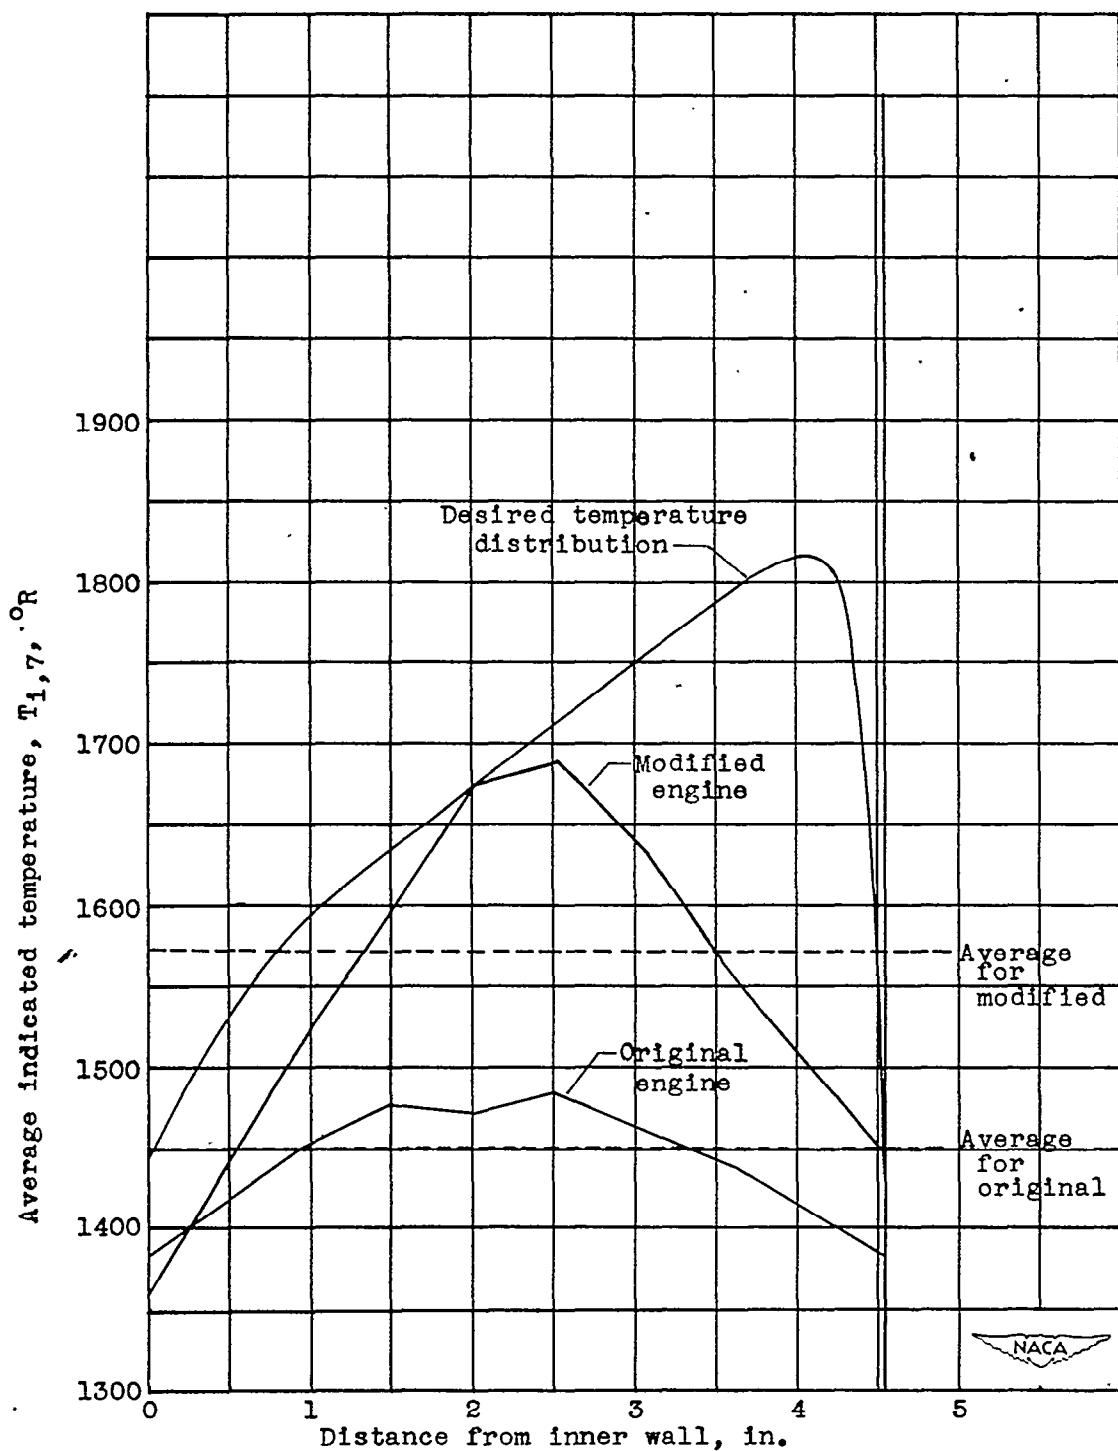

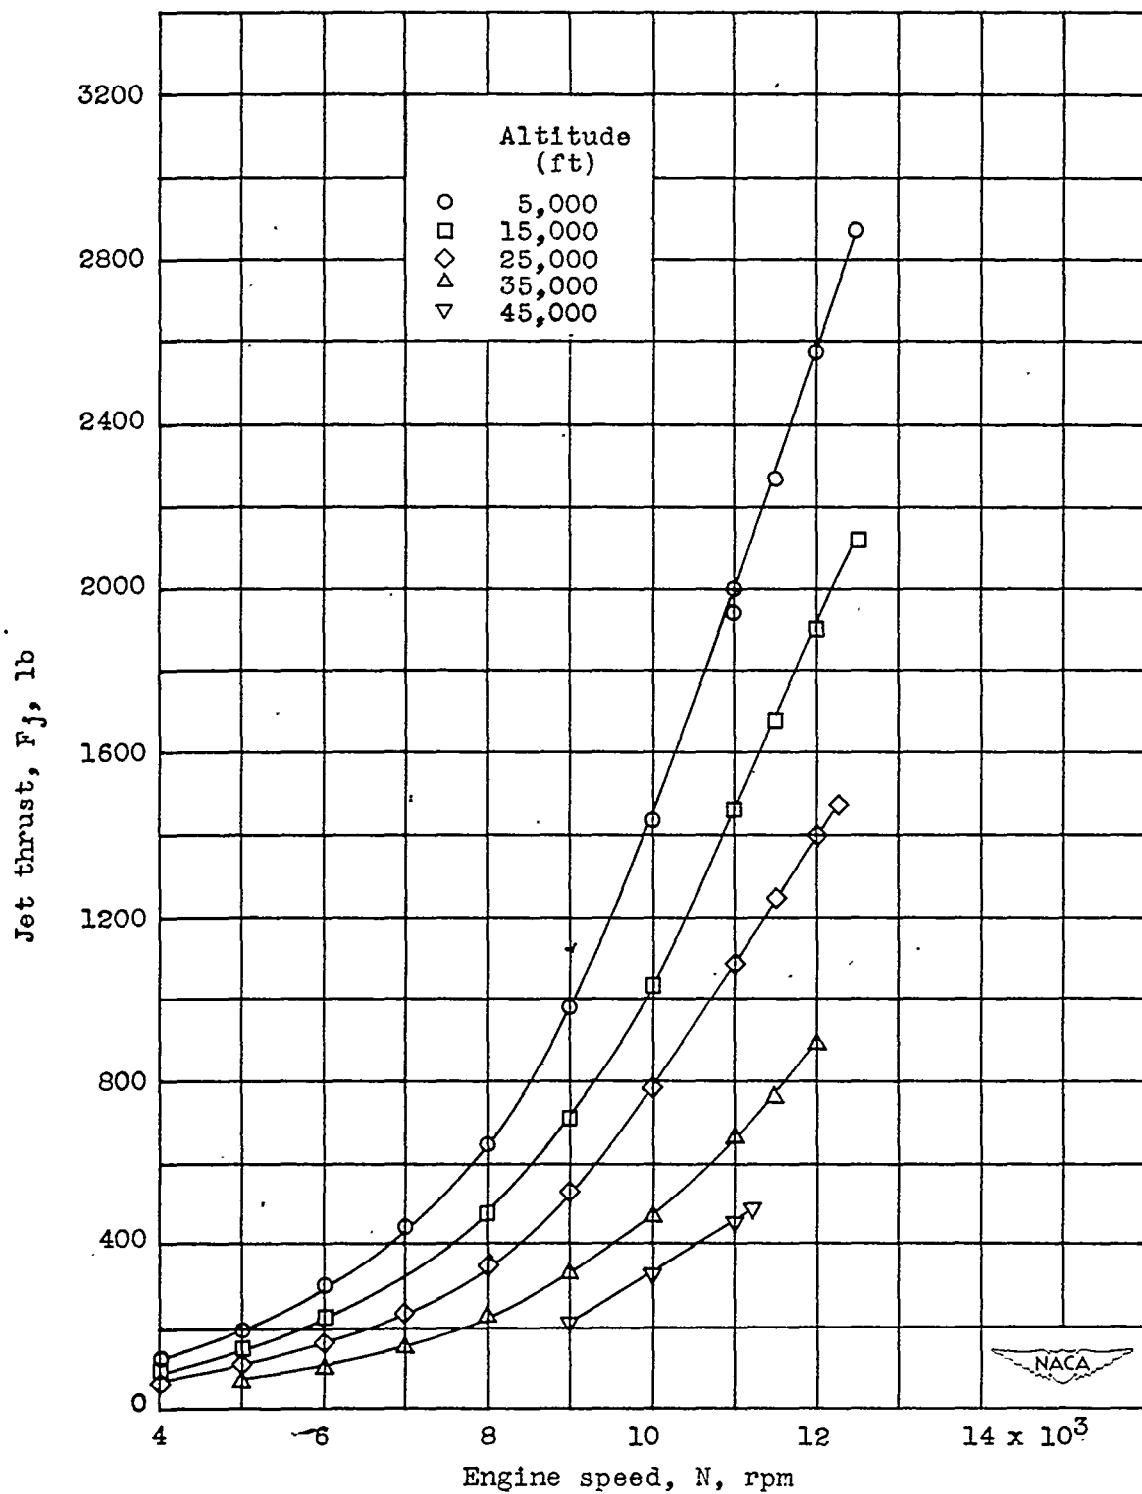

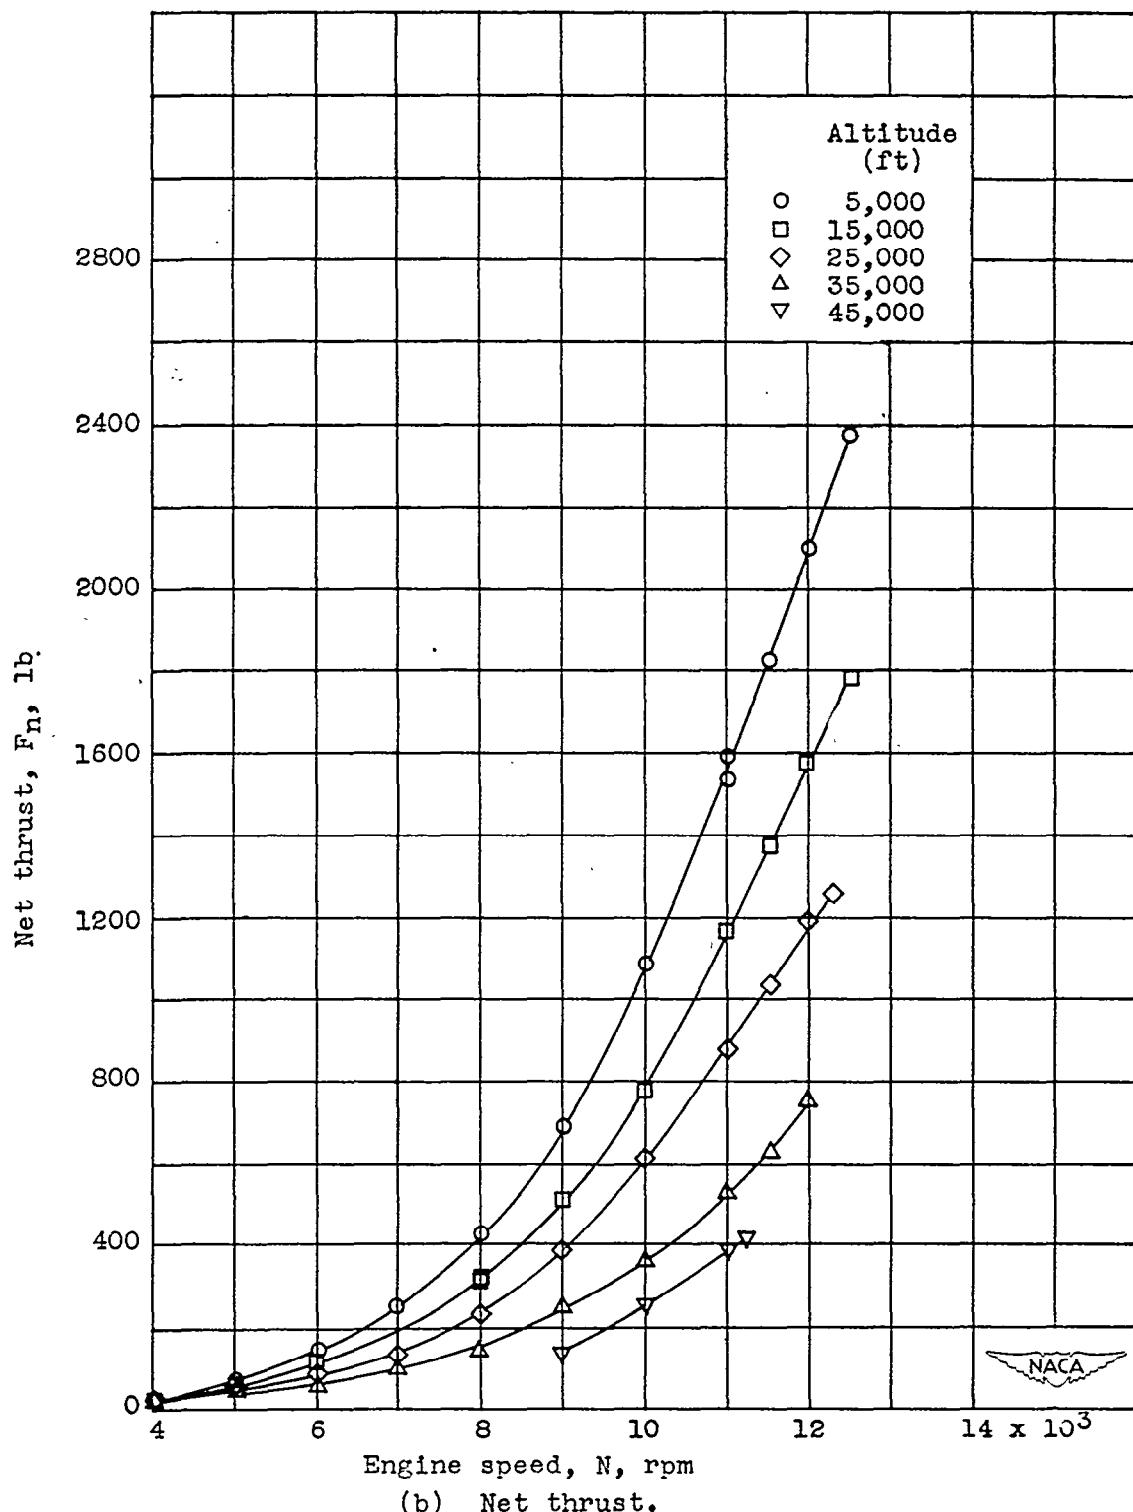

Figure 4. - Comparison of average temperature patterns at turbine outlet for original and modified engines and relation to manufacturer's desired temperature distribution as calculated from blade stress considerations. Altitude, 5000 feet; engine speed, 12,500 rpm; Mach number, 0.25.

(a) Jet thrust.

Figure 5. - Effect of altitude on variation of turbojet engine performance with engine speed. Flight Mach number, 0.25.

(b) Net thrust.

Figure 5. - Continued. Effect of altitude on variation of turbojet engine performance with engine speed. Flight Mach number, 0.25.

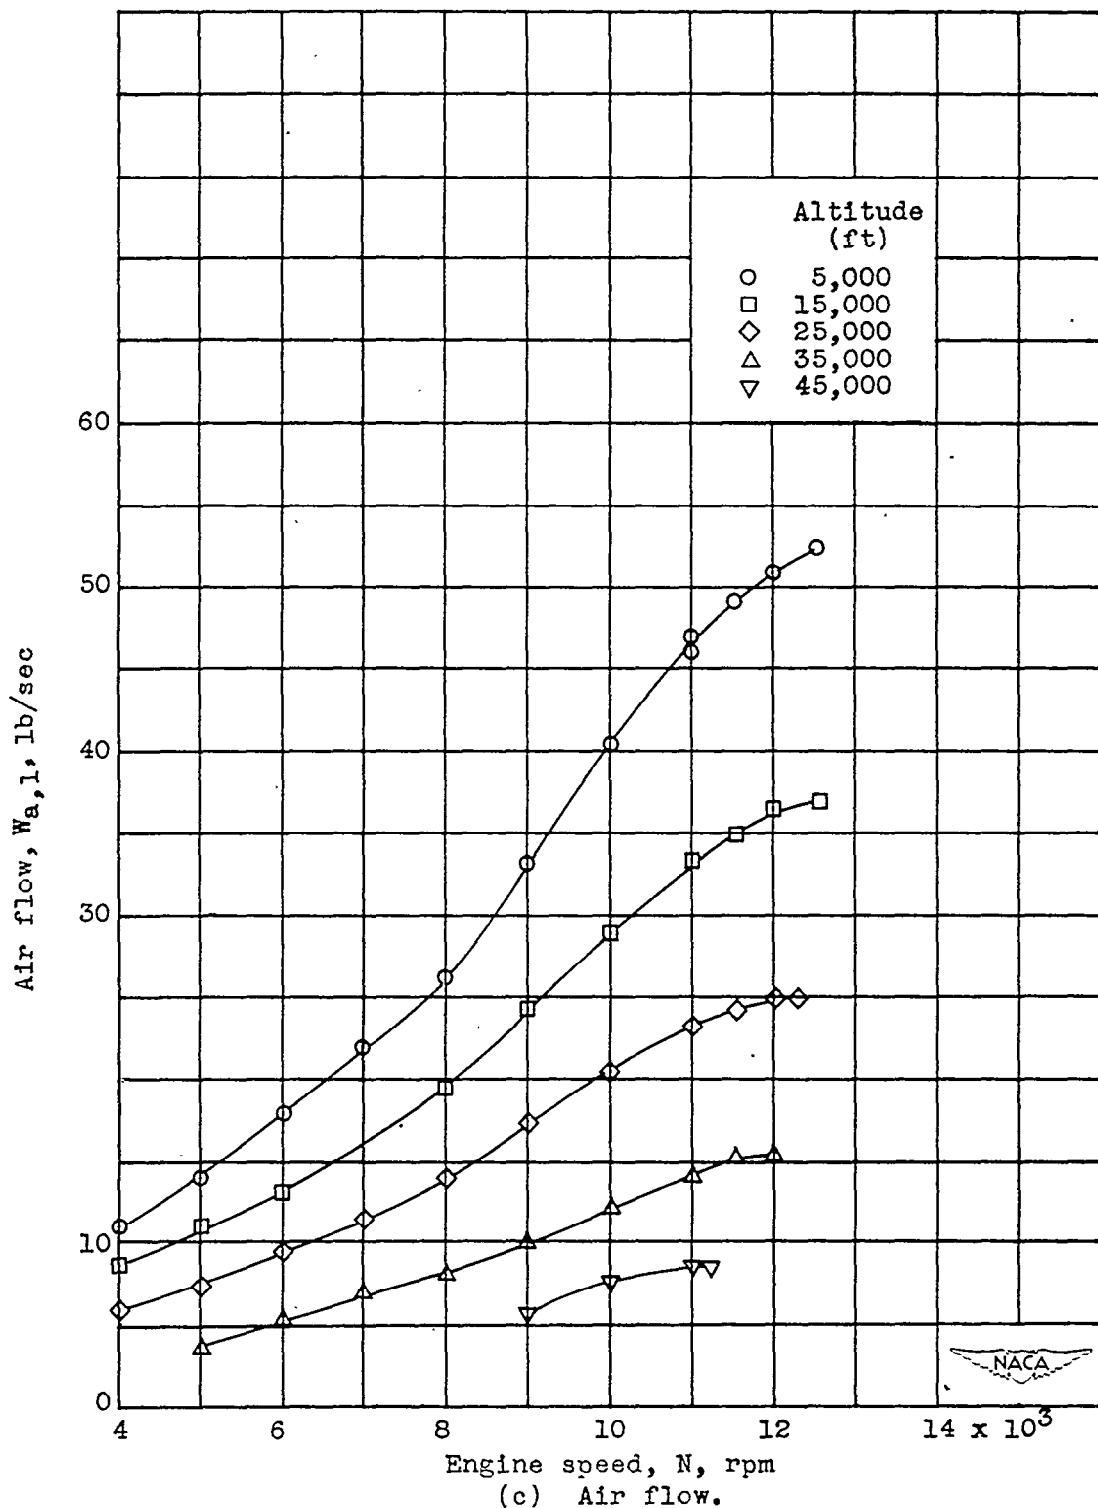

Figure 5. - Continued. Effect of altitude on variation of turbojet engine performance with engine speed. Flight Mach number, 0.25.

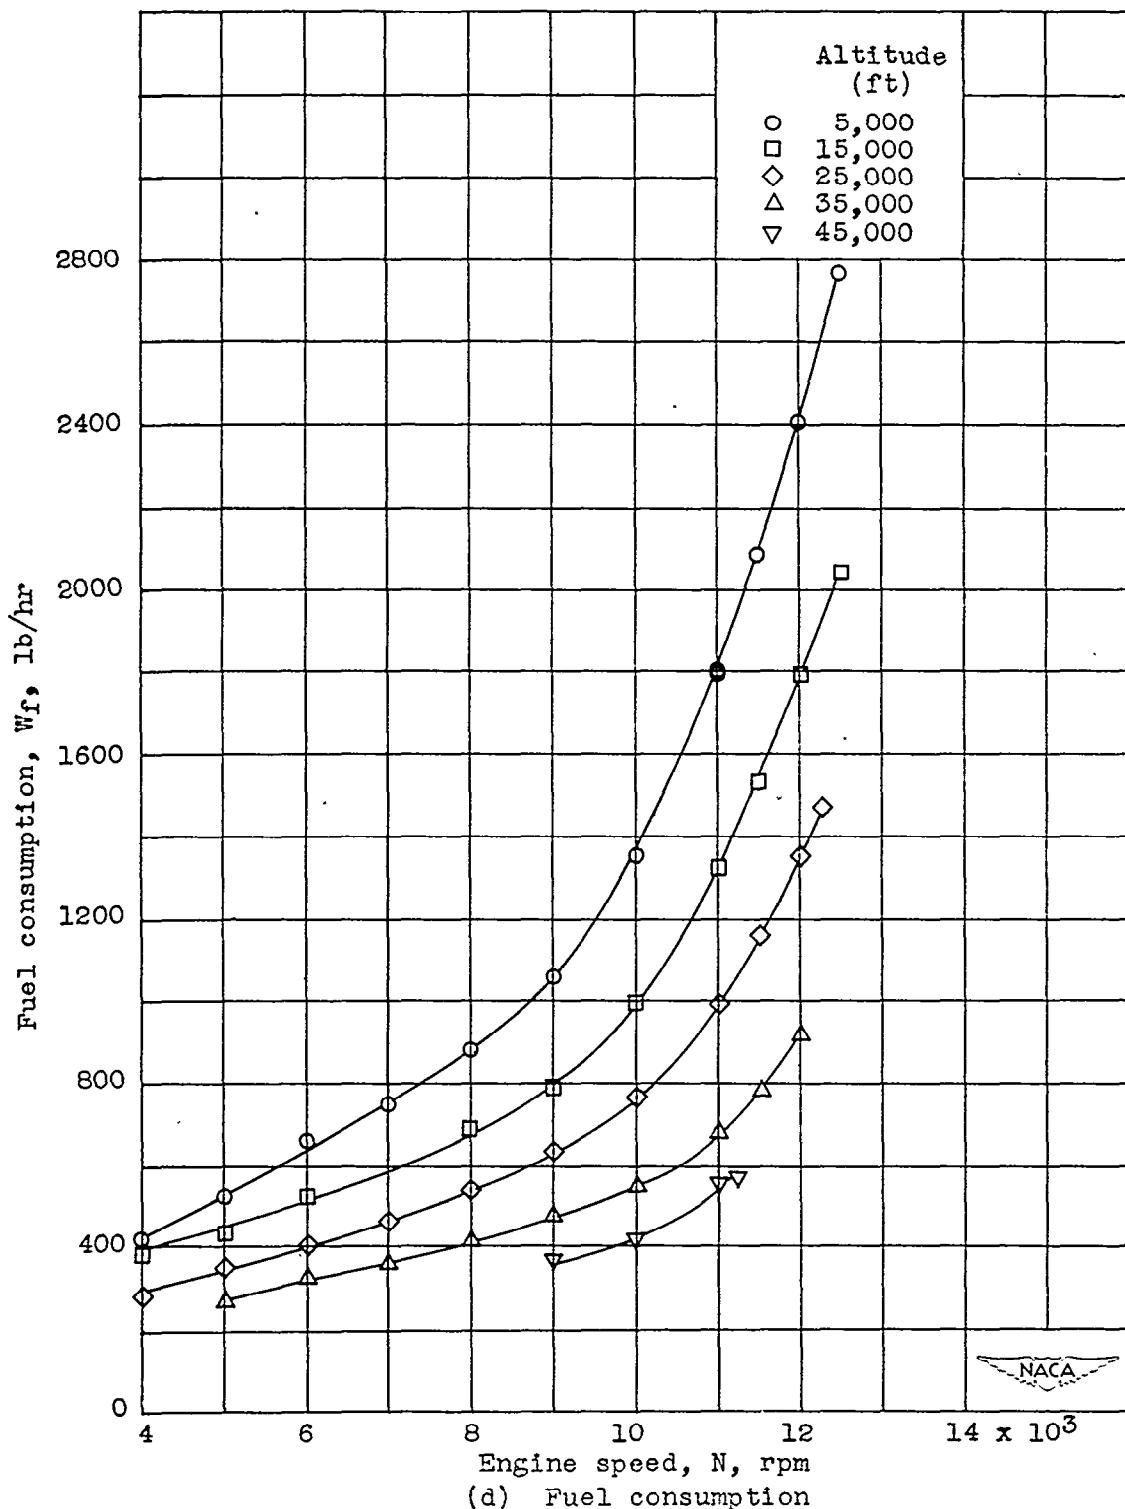

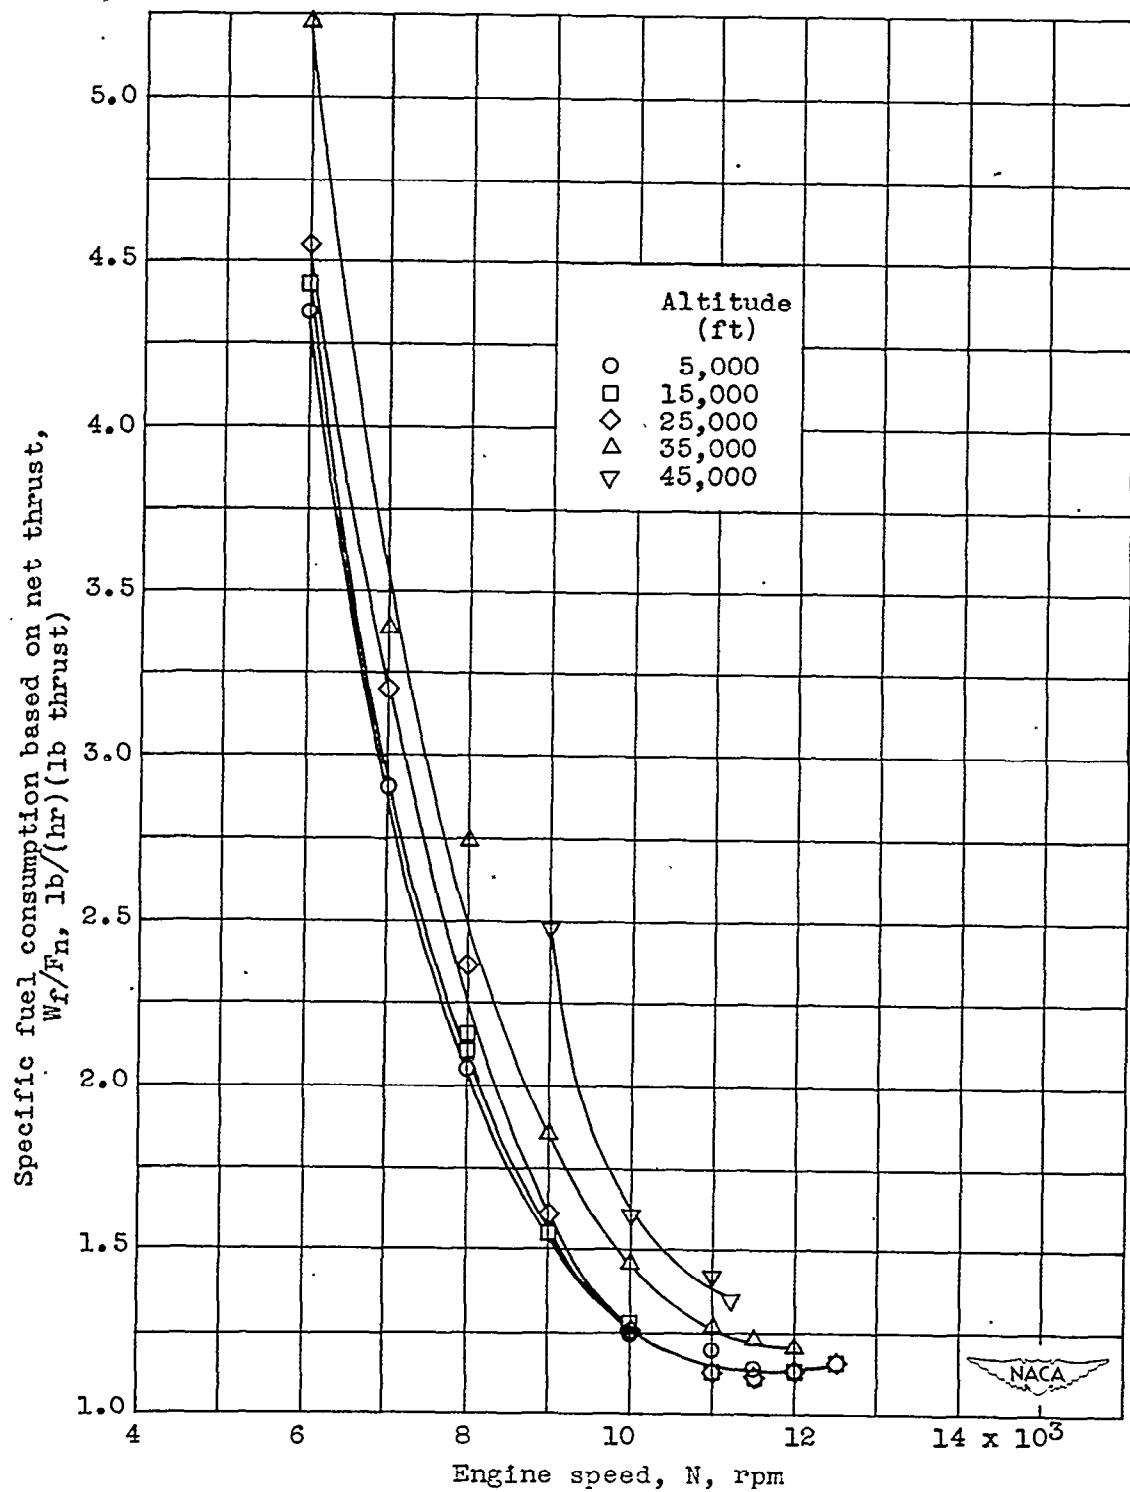

Figure 5. - Continued. Effect of altitude on variation of turbojet engine performance with engine speed. Flight Mach number, 0.25.

(e) Specific fuel consumption based on net thrust.

Figure 5. - Continued. Effect of altitude on variation of turbojet engine performance with engine speed. Flight Mach number, 0.25.

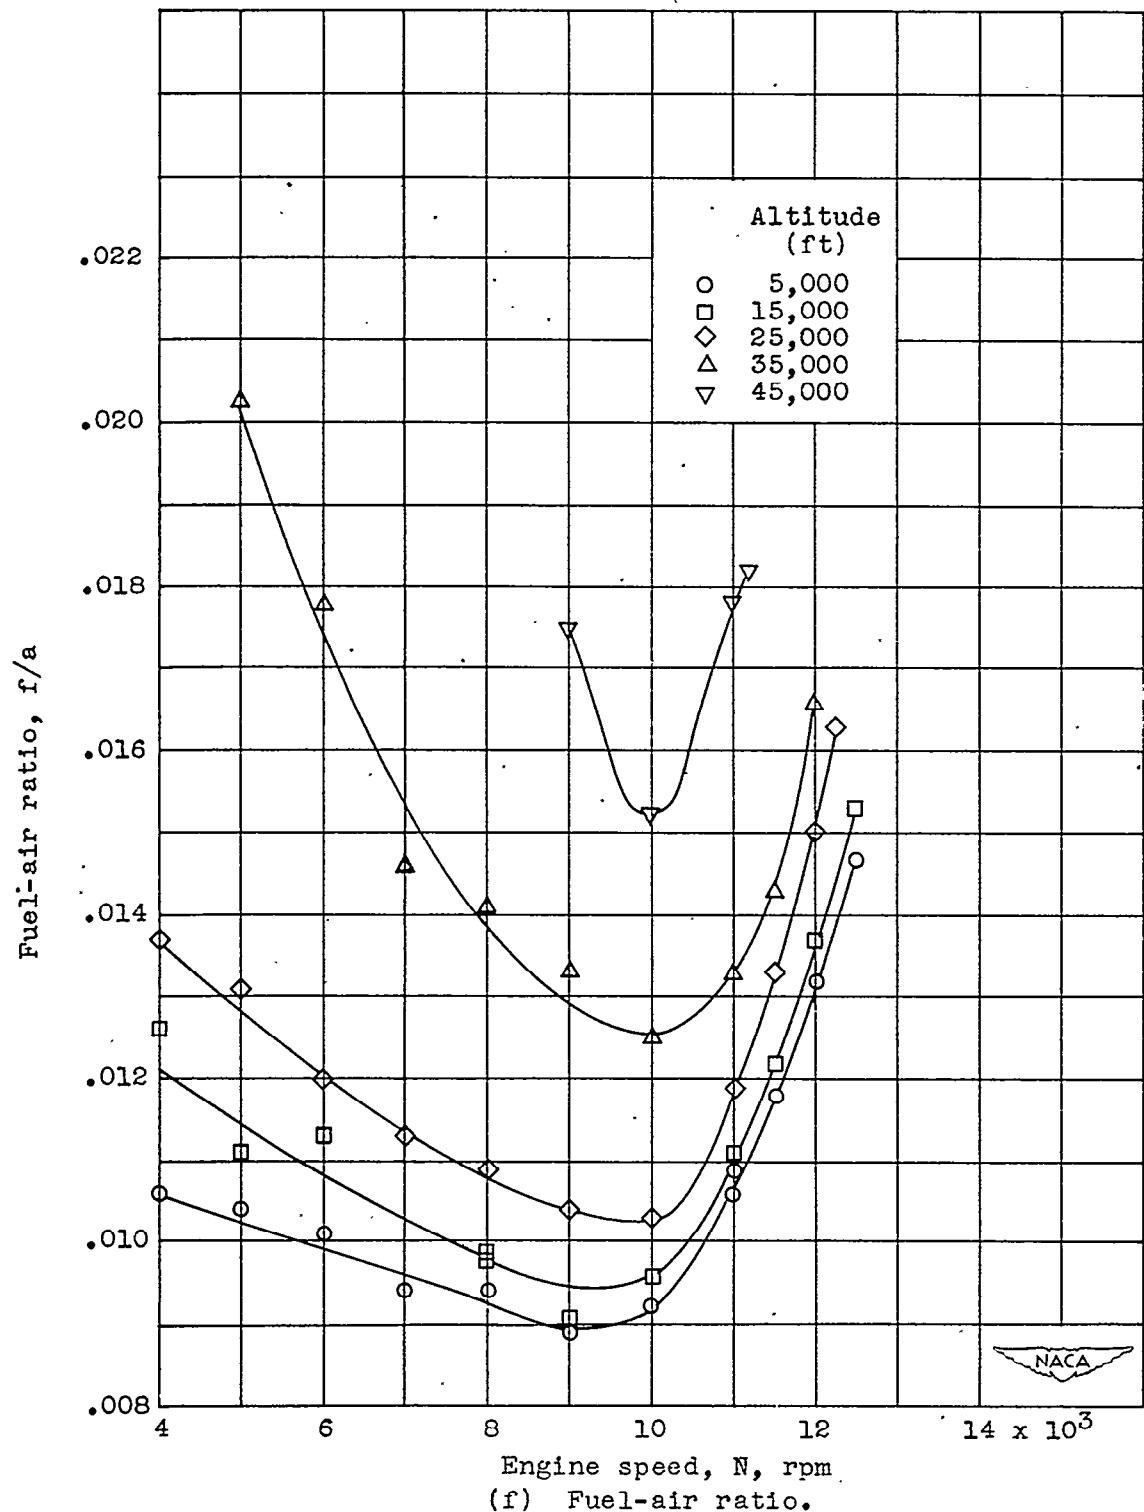

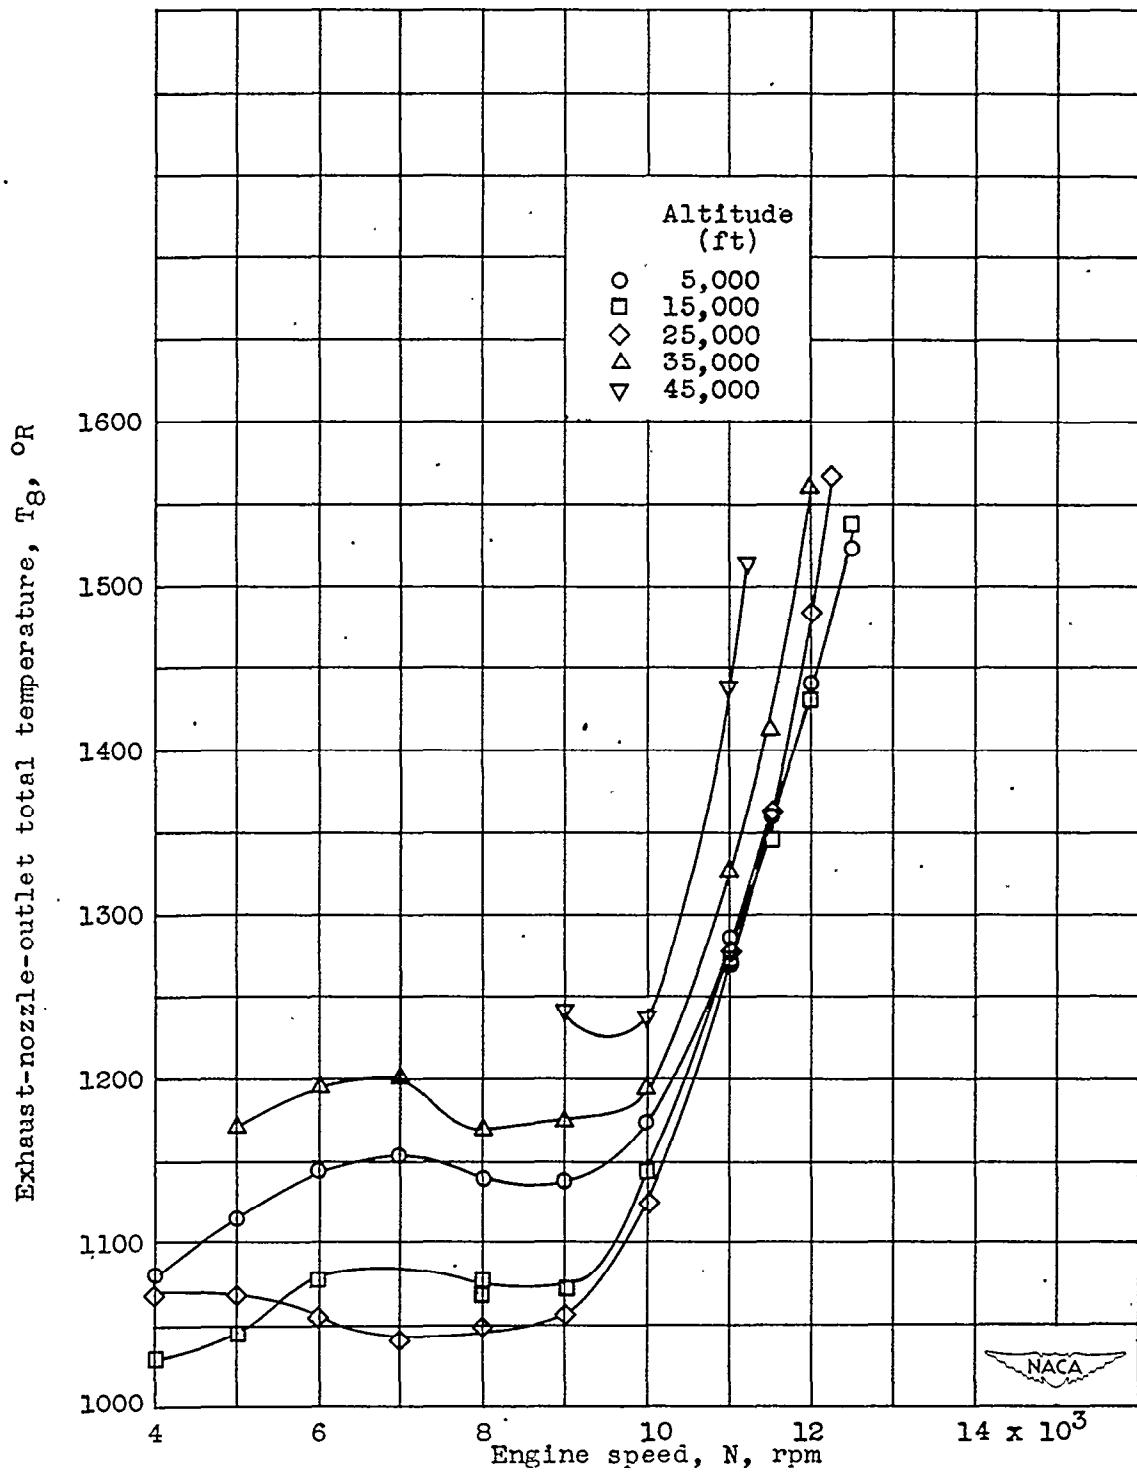

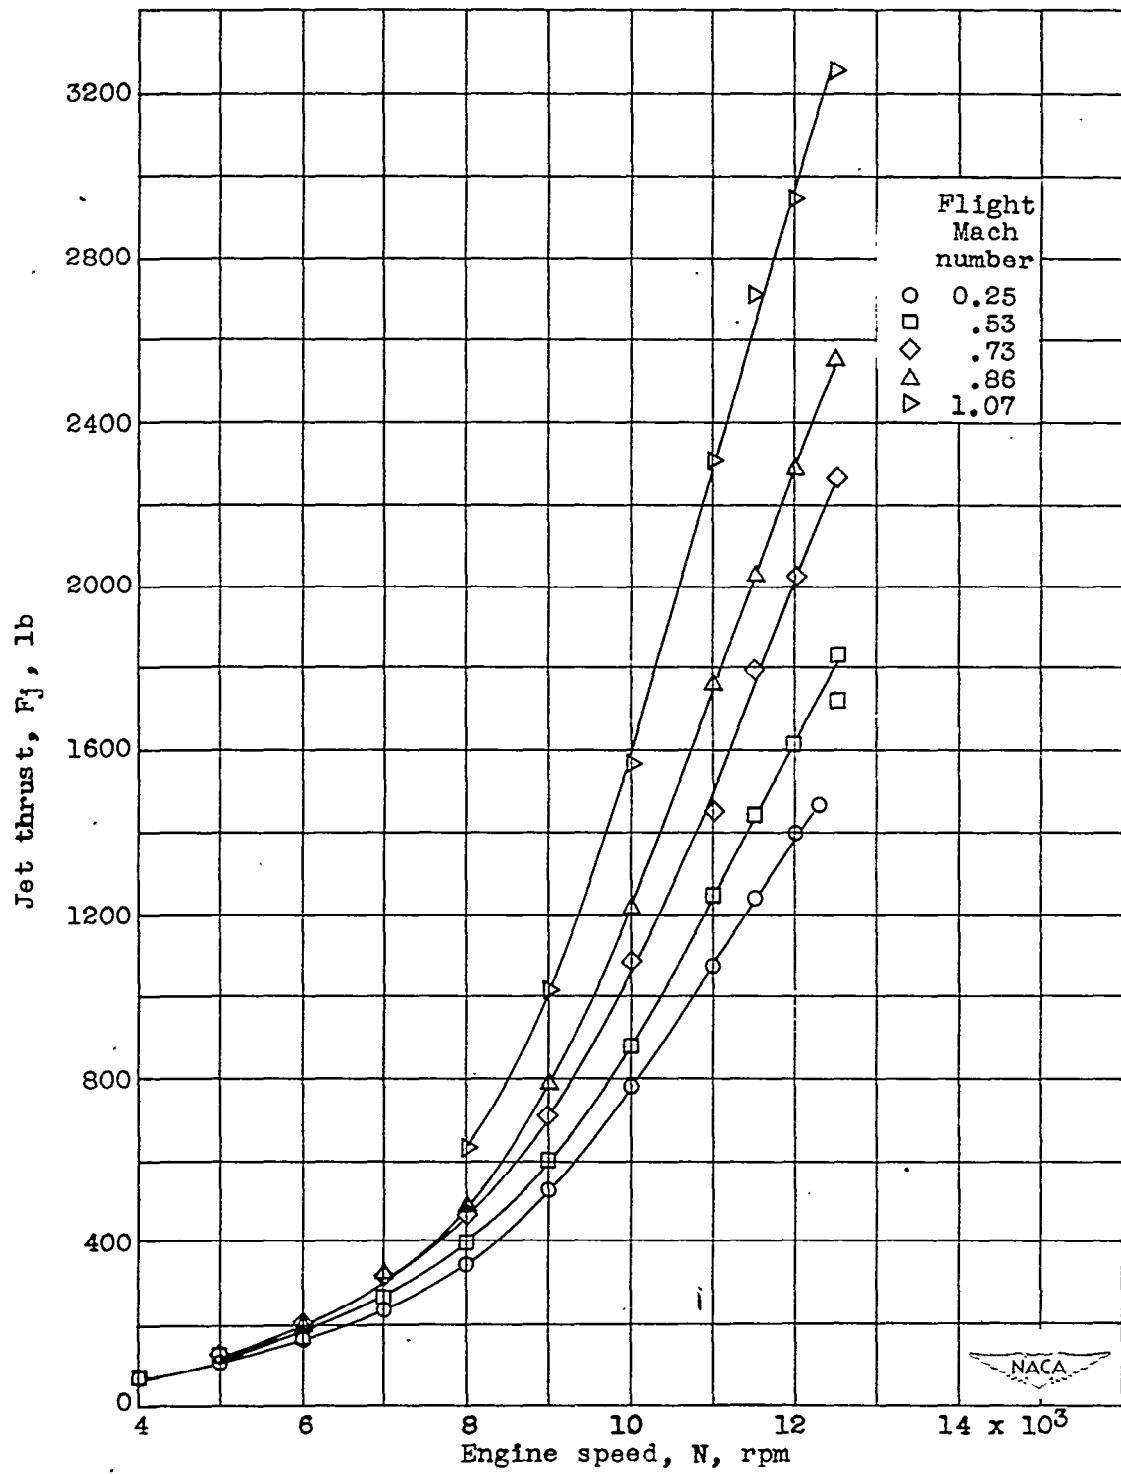

Figure 5. - Continued. Effect of altitude on variation of turbojet engine performance with engine speed. Flight Mach number, 0.25.

(g) Exhaust-nozzle-outlet total temperature.

Figure 5. - Concluded. Effect of altitude on variation of turbojet engine performance with engine speed. Flight Mach number, 0.25.

(a) Jet thrust.

Figure 6. - Effect of flight Mach number on variation of turbojet engine performance with engine speed. Altitude, 25,000 feet.

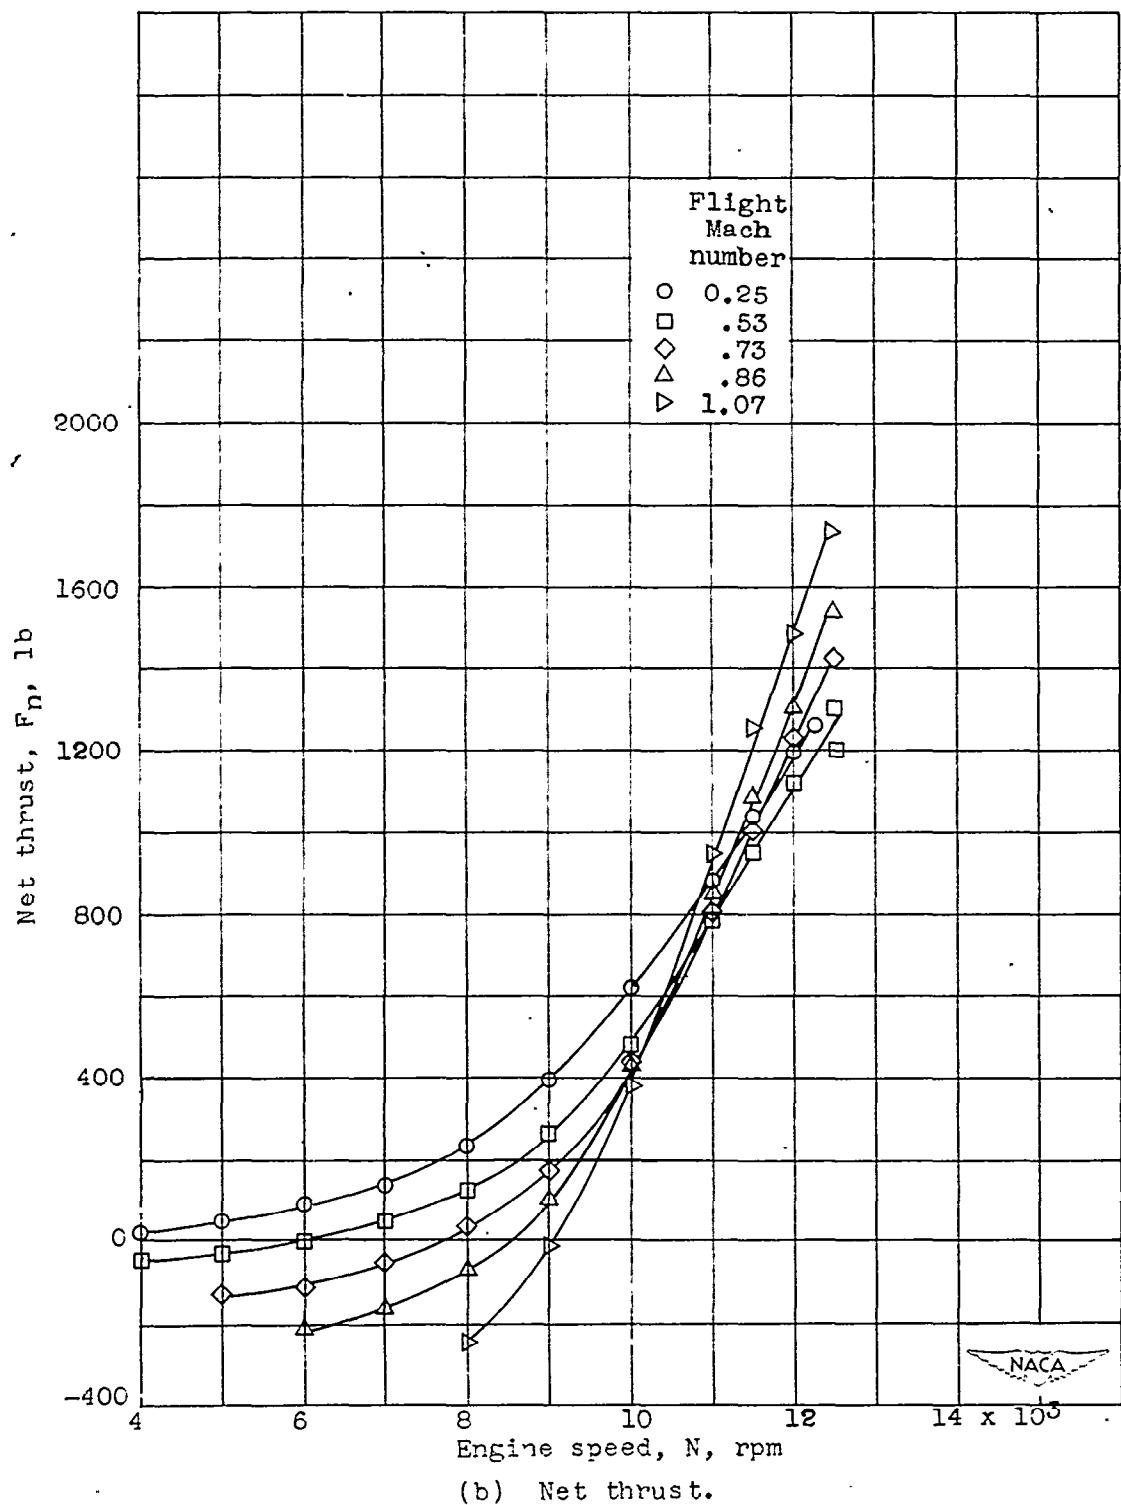

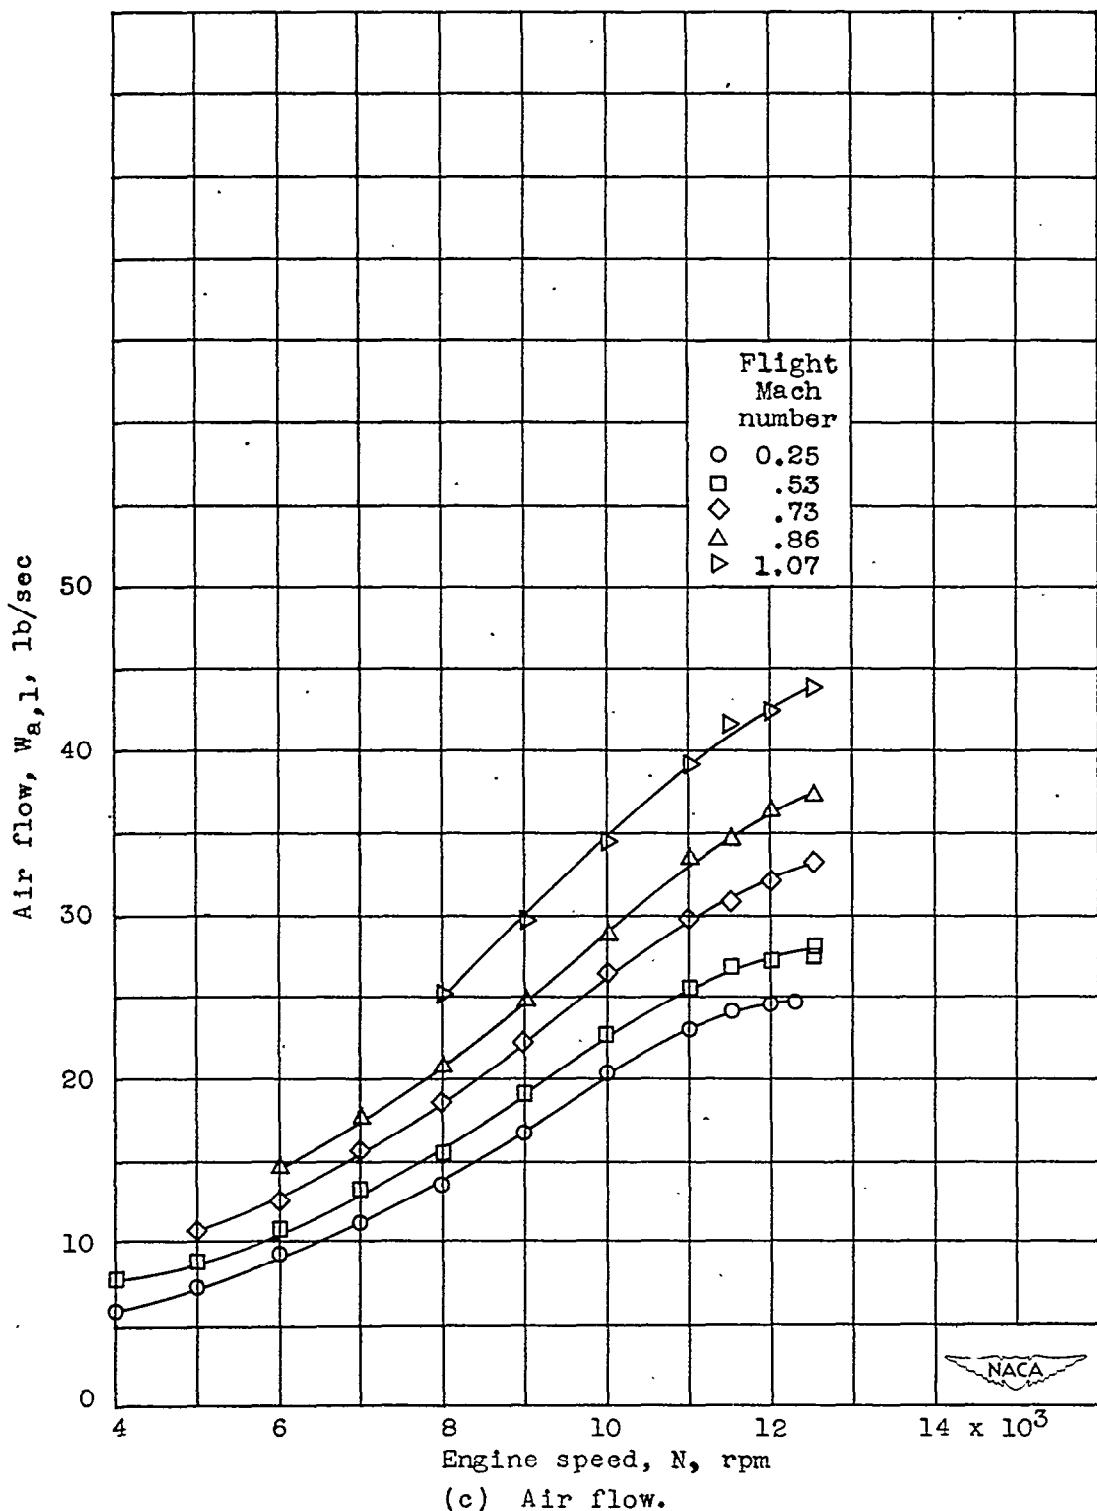

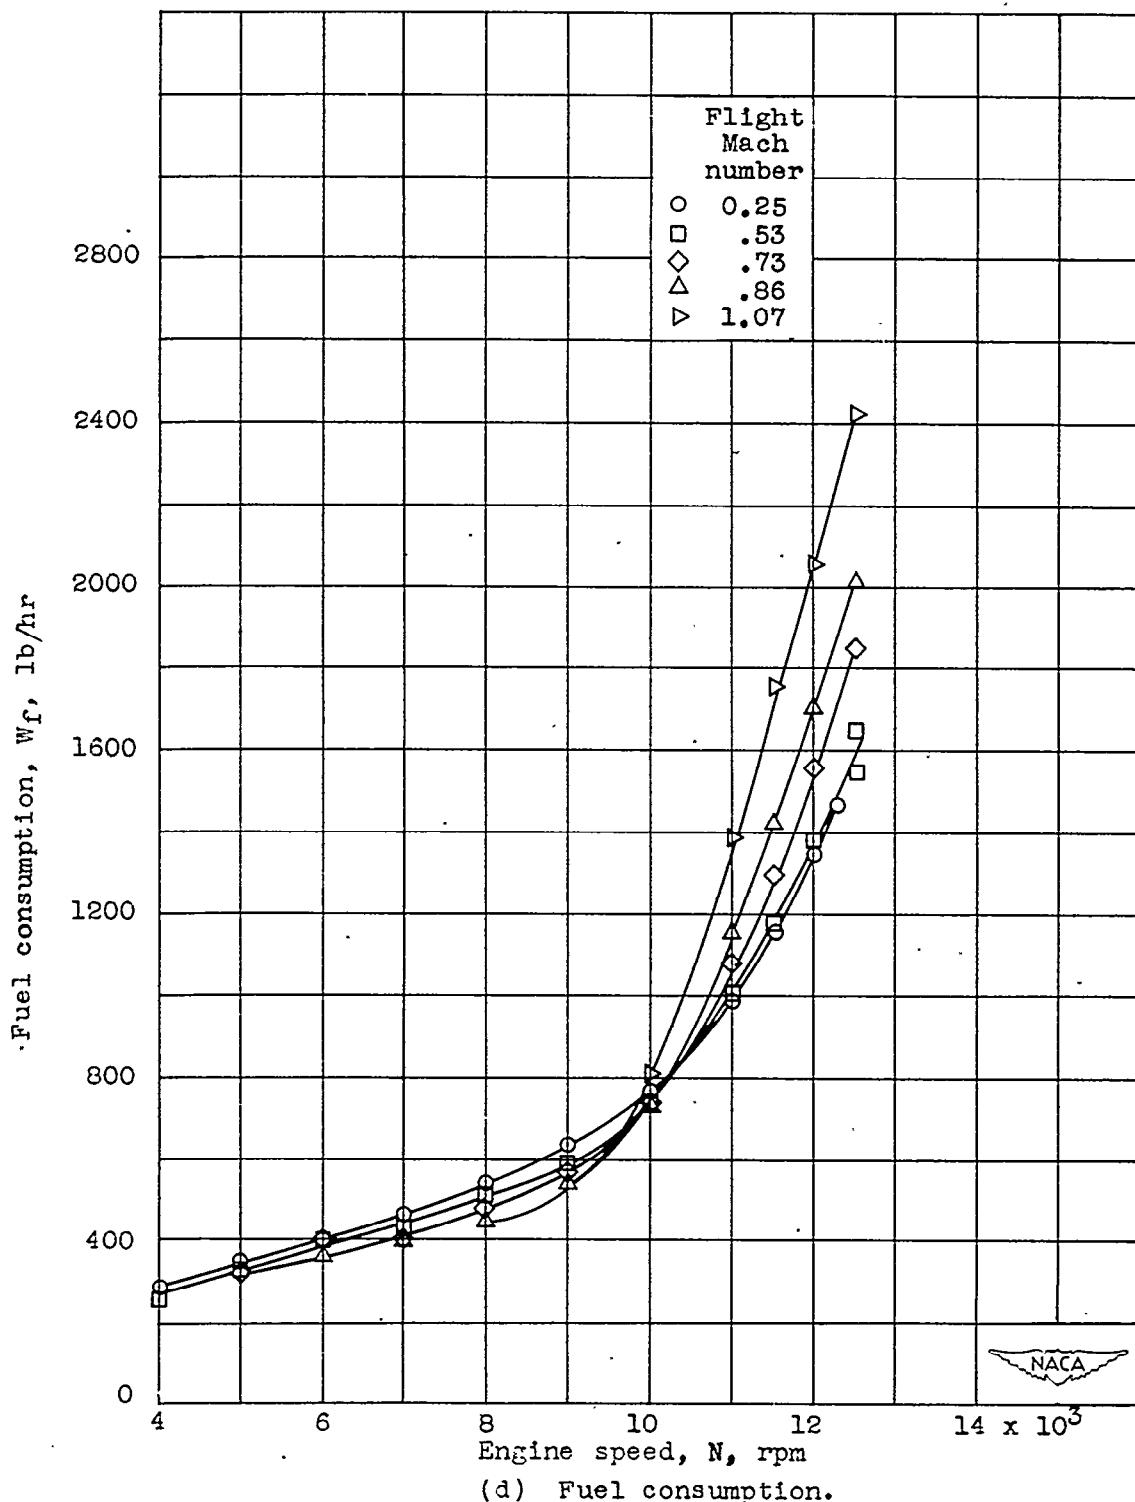

Figure 6. - Continued. Effect of flight Mach number on variation of turbojet engine performance with engine speed.
Altitude, 25,000 feet.

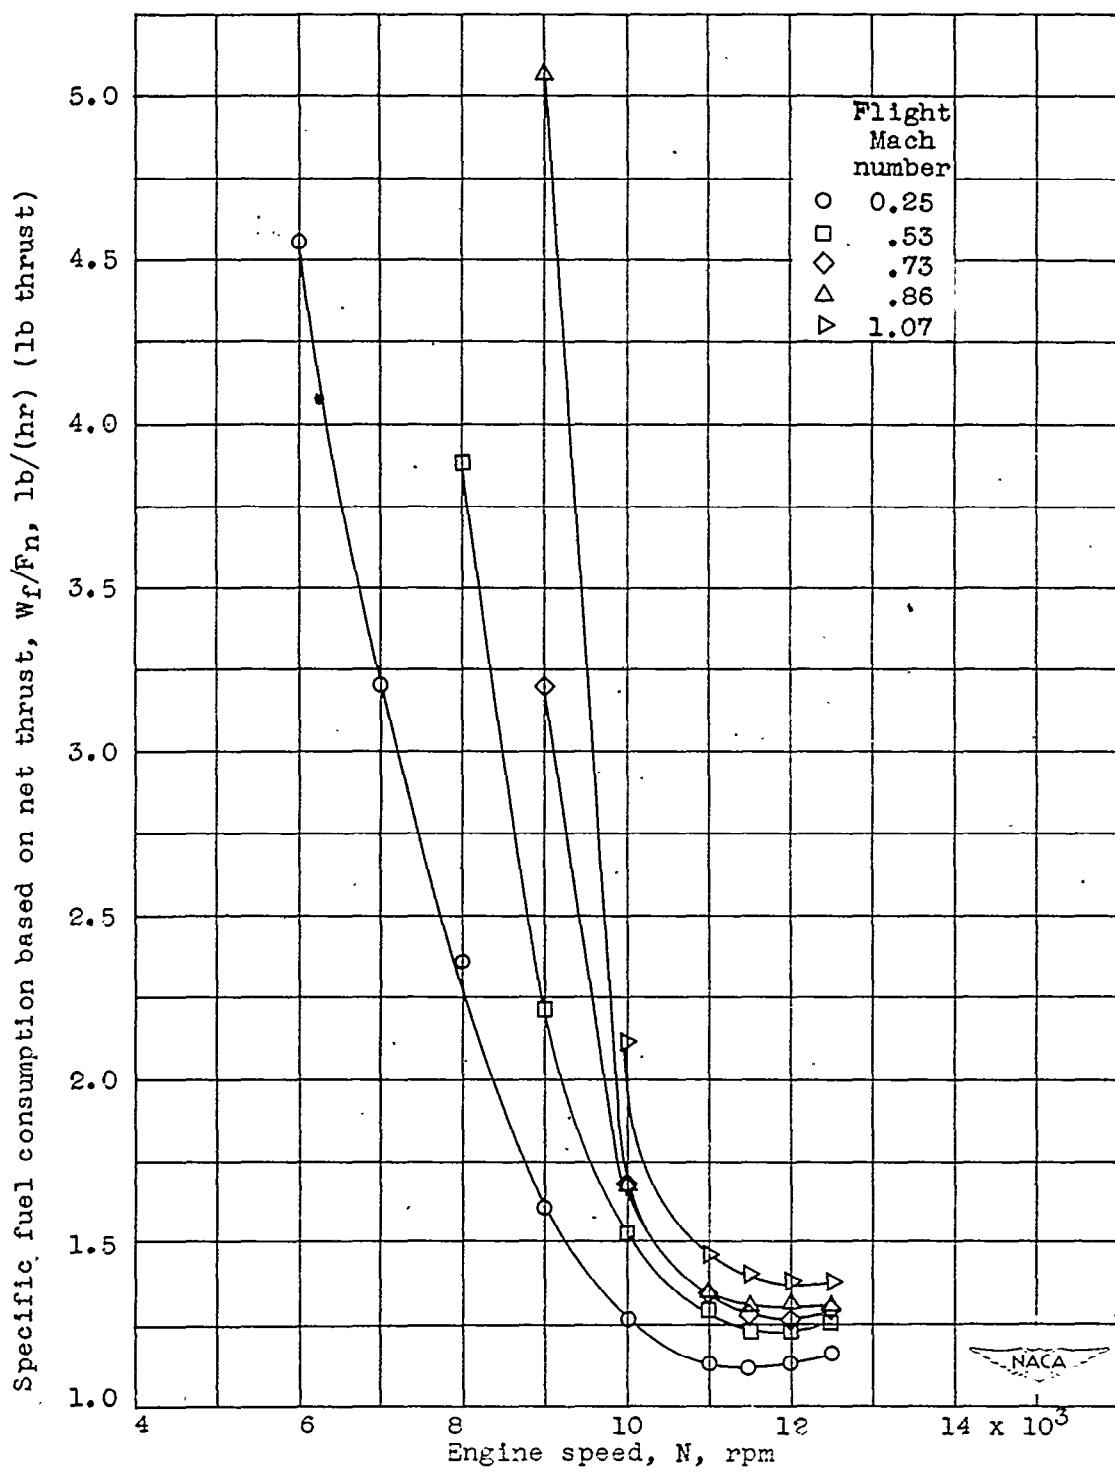

(c) Air flow.

Figure 6. - Continued. Effect of flight Mach number on variation of turbojet engine performance with engine speed.
Altitude, 25,000 feet.

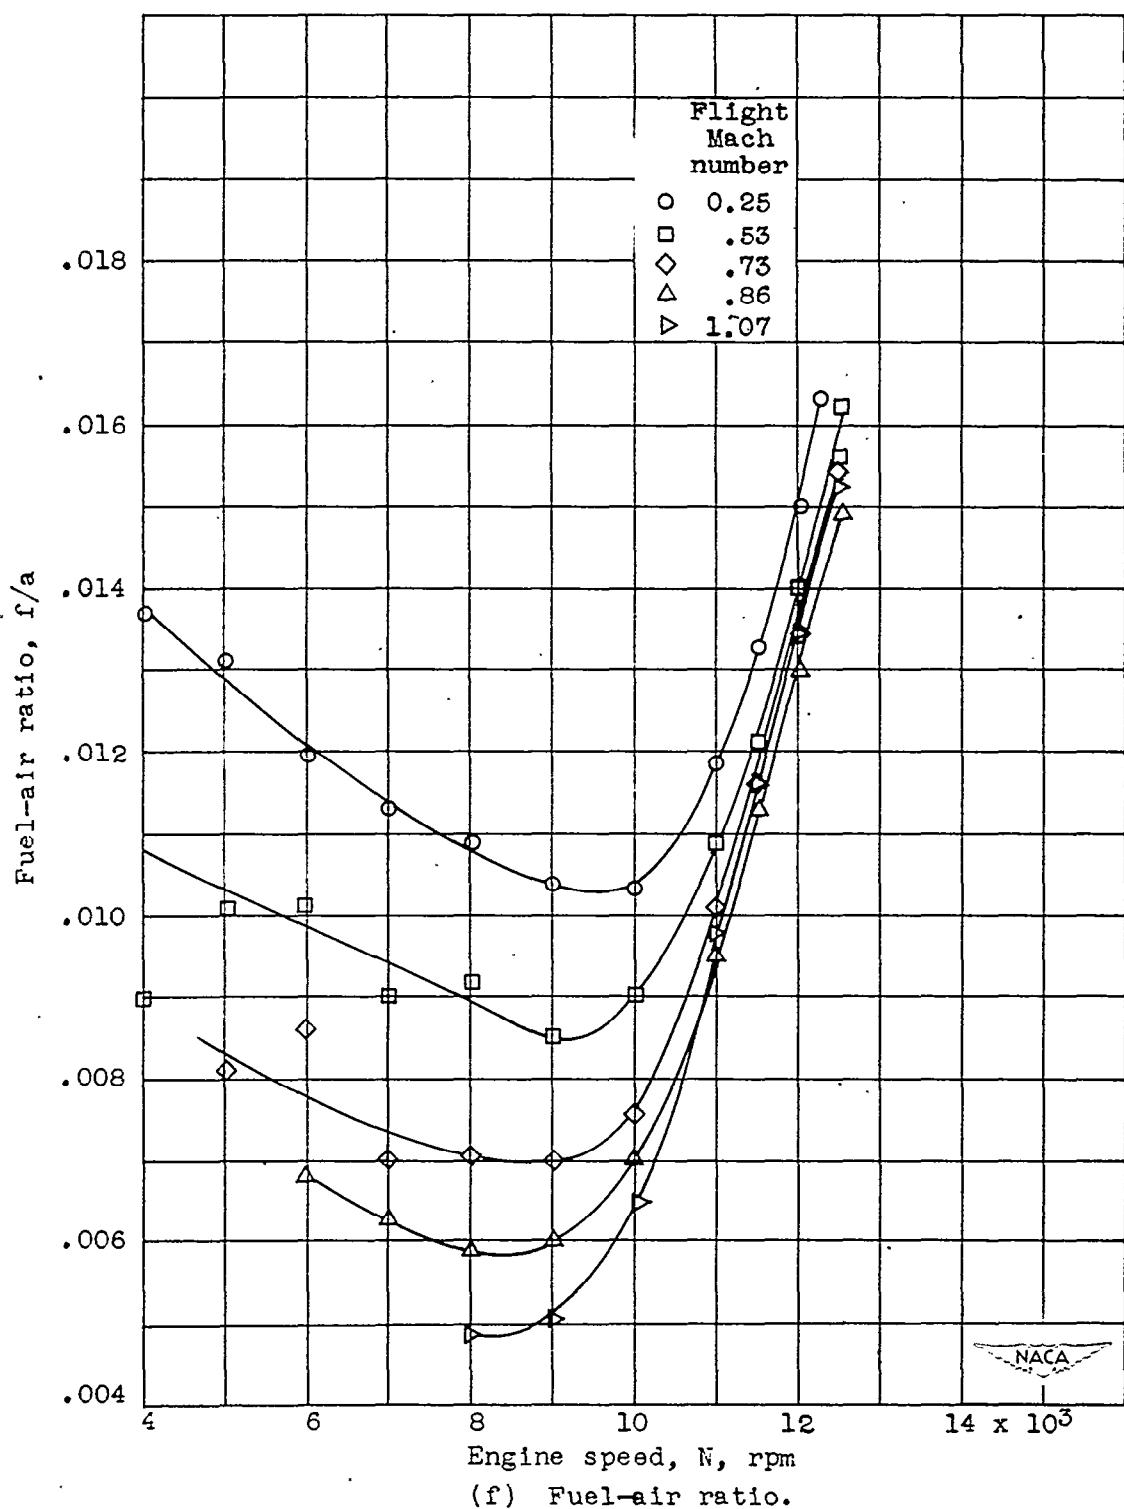

(d) Fuel consumption.

Figure 6. - Continued. Effect of flight Mach number on variation of turbojet engine performance with engine speed.
Altitude, 25,000 feet.

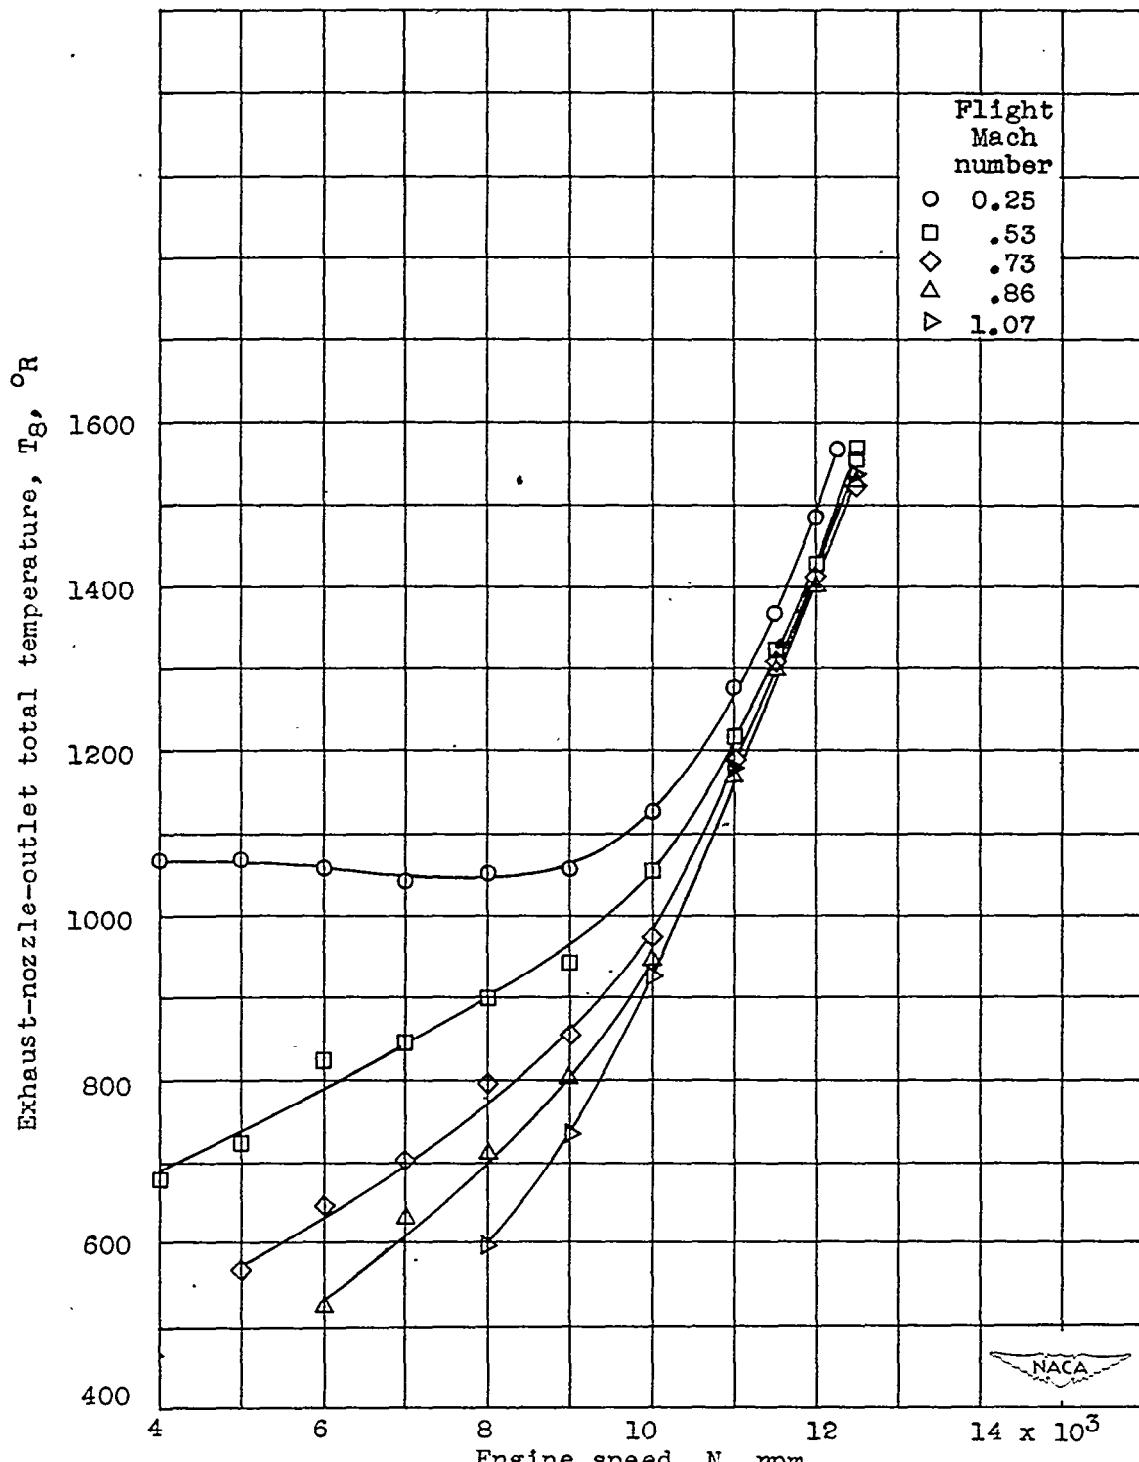

(e) Specific fuel consumption based on net thrust.

Figure 6. - Continued. Effect of flight Mach number on variation of turbojet engine performance with engine speed.
Altitude, 25,000 feet.

(f) Fuel-air ratio.

Figure 6. - Continued. Effect of flight Mach number on variation of turbojet engine performance with engine speed.
Altitude, 25,000 feet.

(g) Exhaust-nozzle-outlet total temperature.

Figure 6. - Concluded. Effect of flight Mach number on variation of turbojet engine performance with engine speed. Altitude, 25,000 feet.

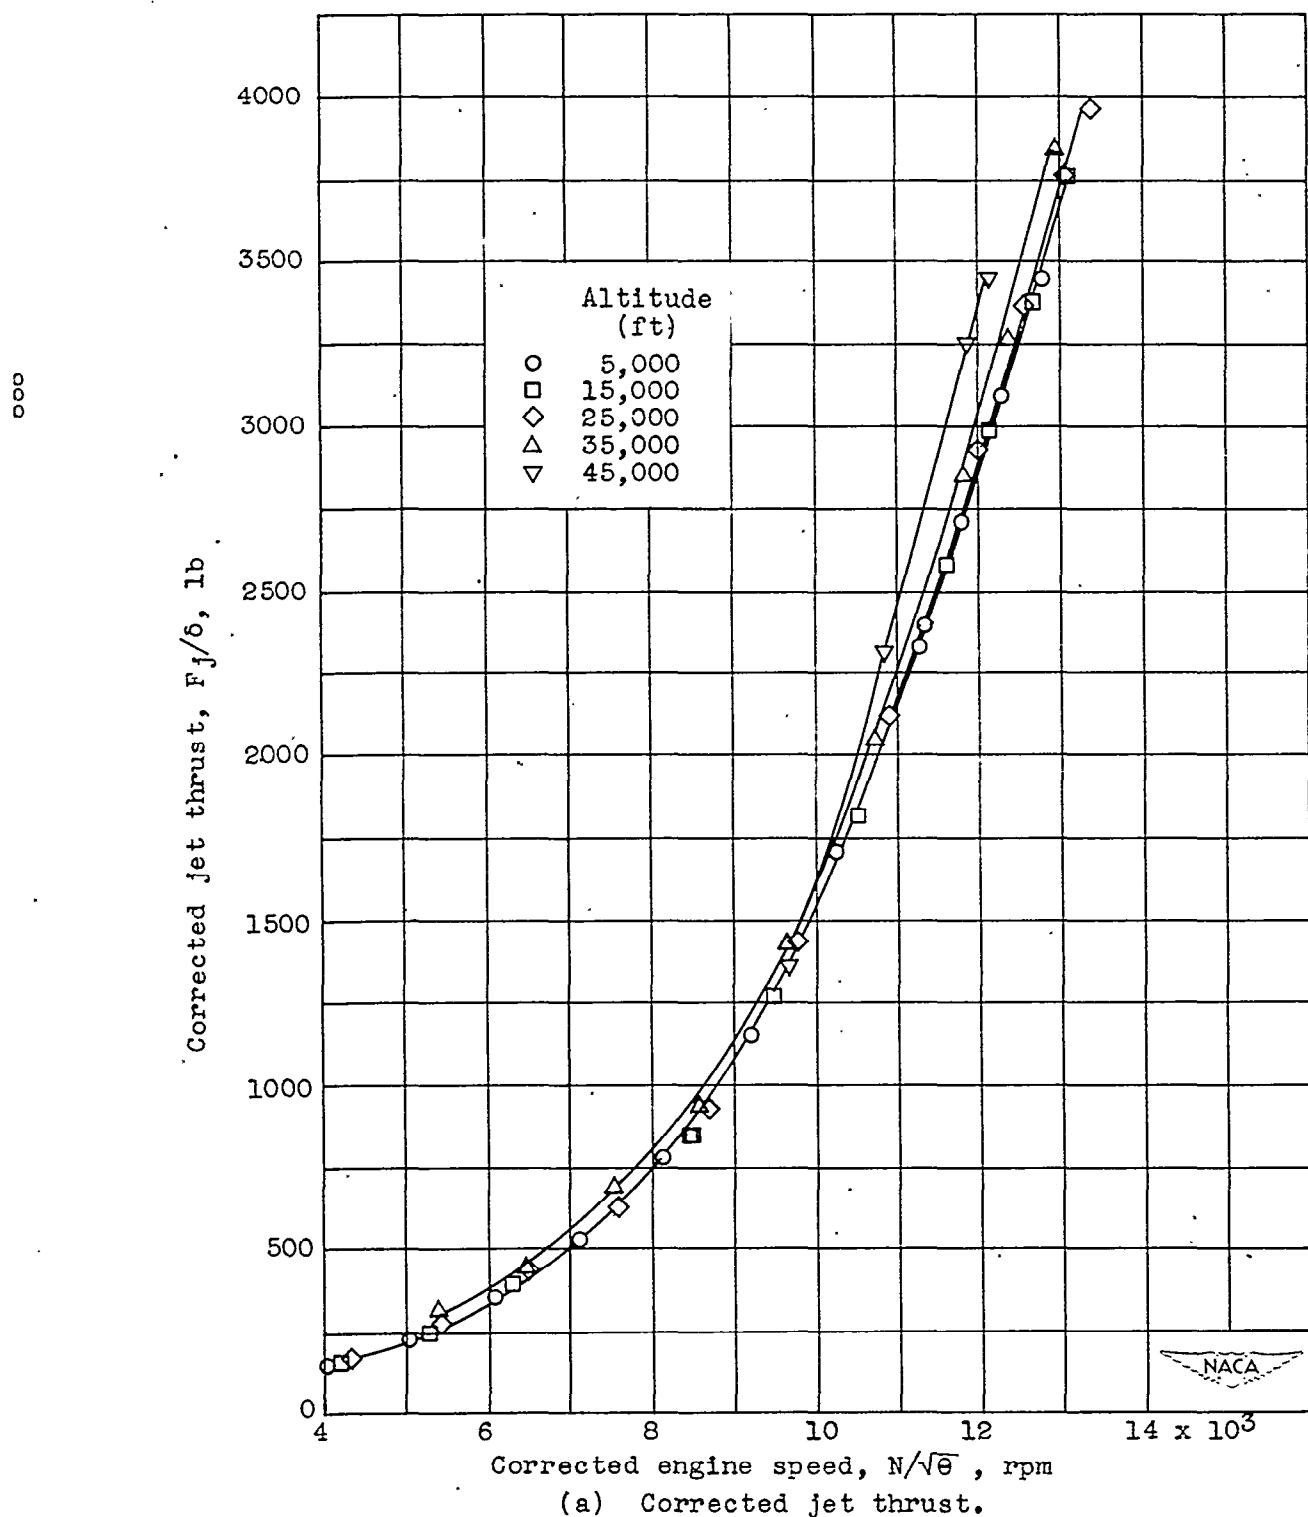

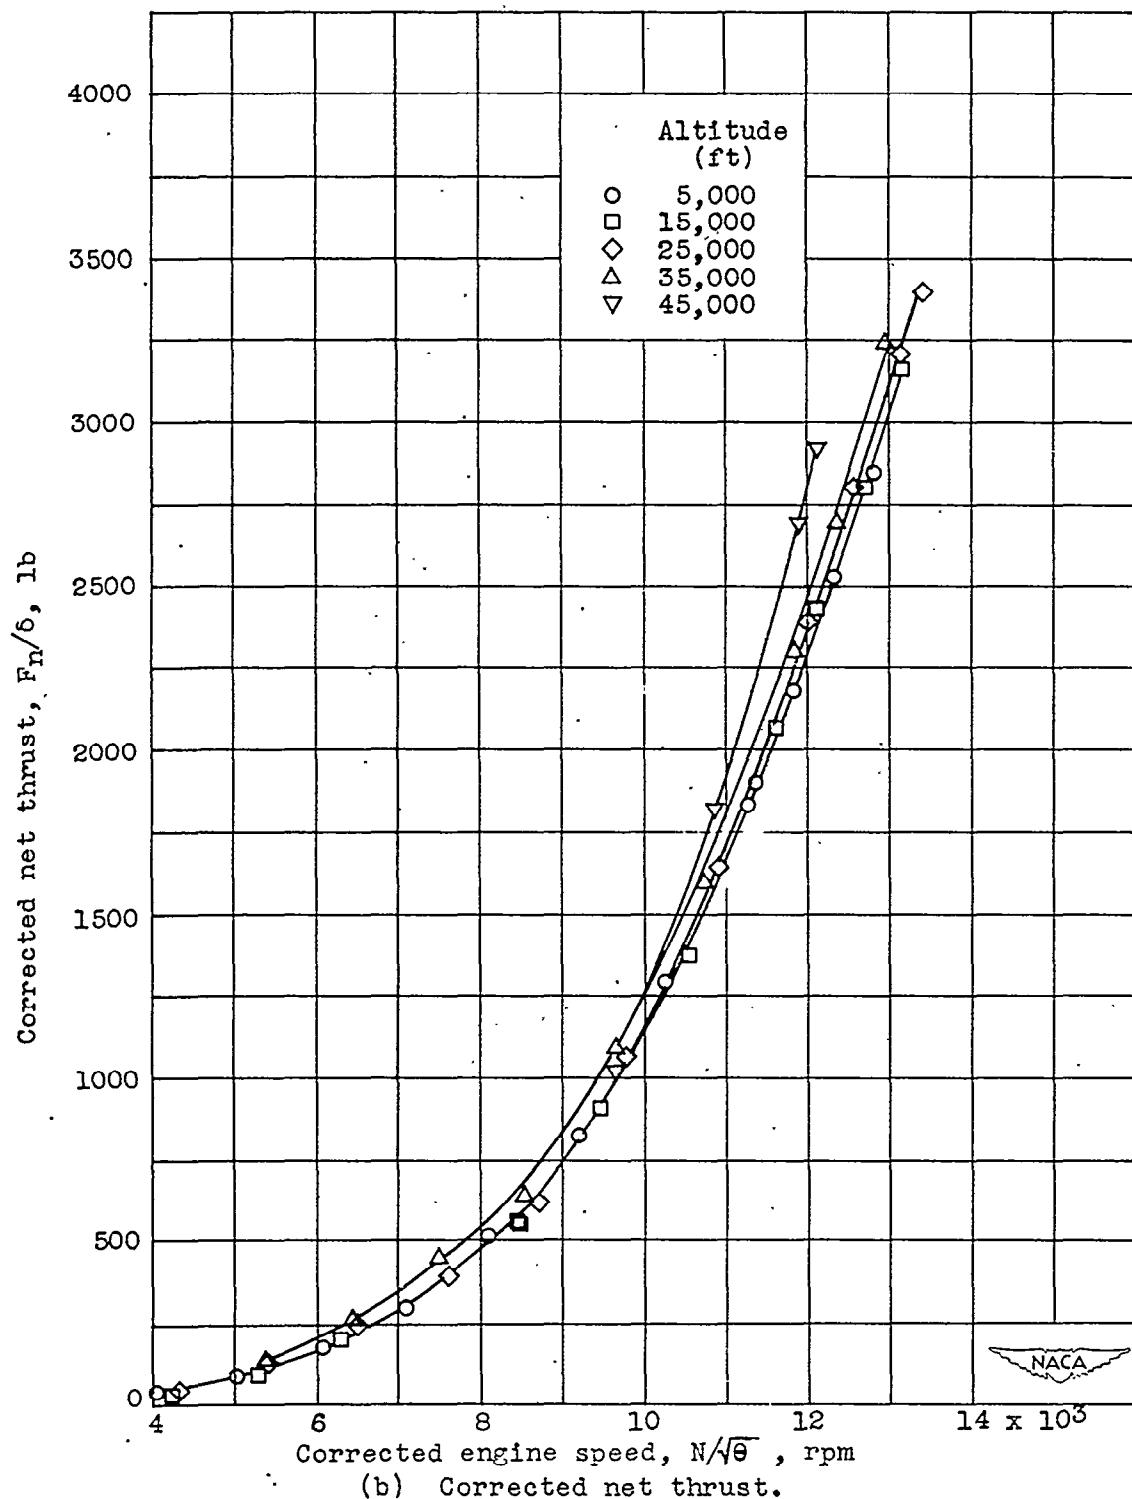

Figure 7. - Effect of altitude on variation of generalized turbojet engine performance with corrected engine speed. Flight Mach number, 0.25.

CONFIDENTIAL

(b) Corrected net thrust.

Figure 7. - Continued. Effect of altitude on variation of generalized turbojet engine performance with corrected engine speed. Flight Mach number, 0.25.

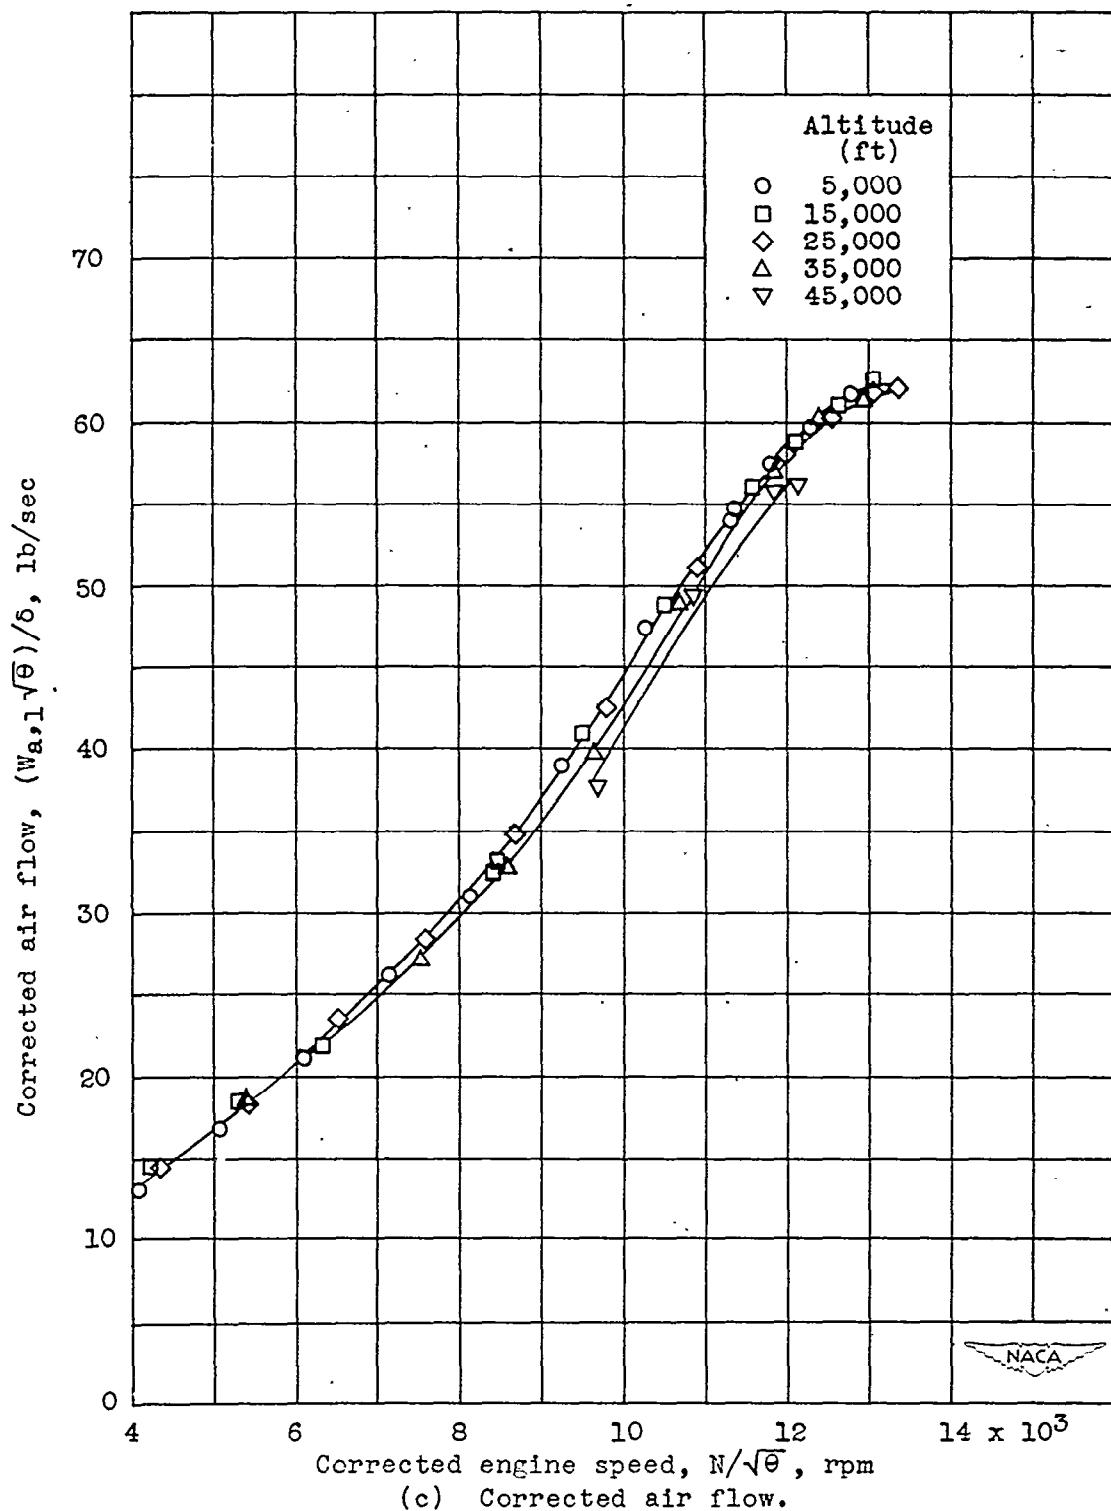

Figure 7. - Continued. Effect of altitude on variation of generalized turbojet engine performance with corrected engine speed. Flight Mach number, 0.25.

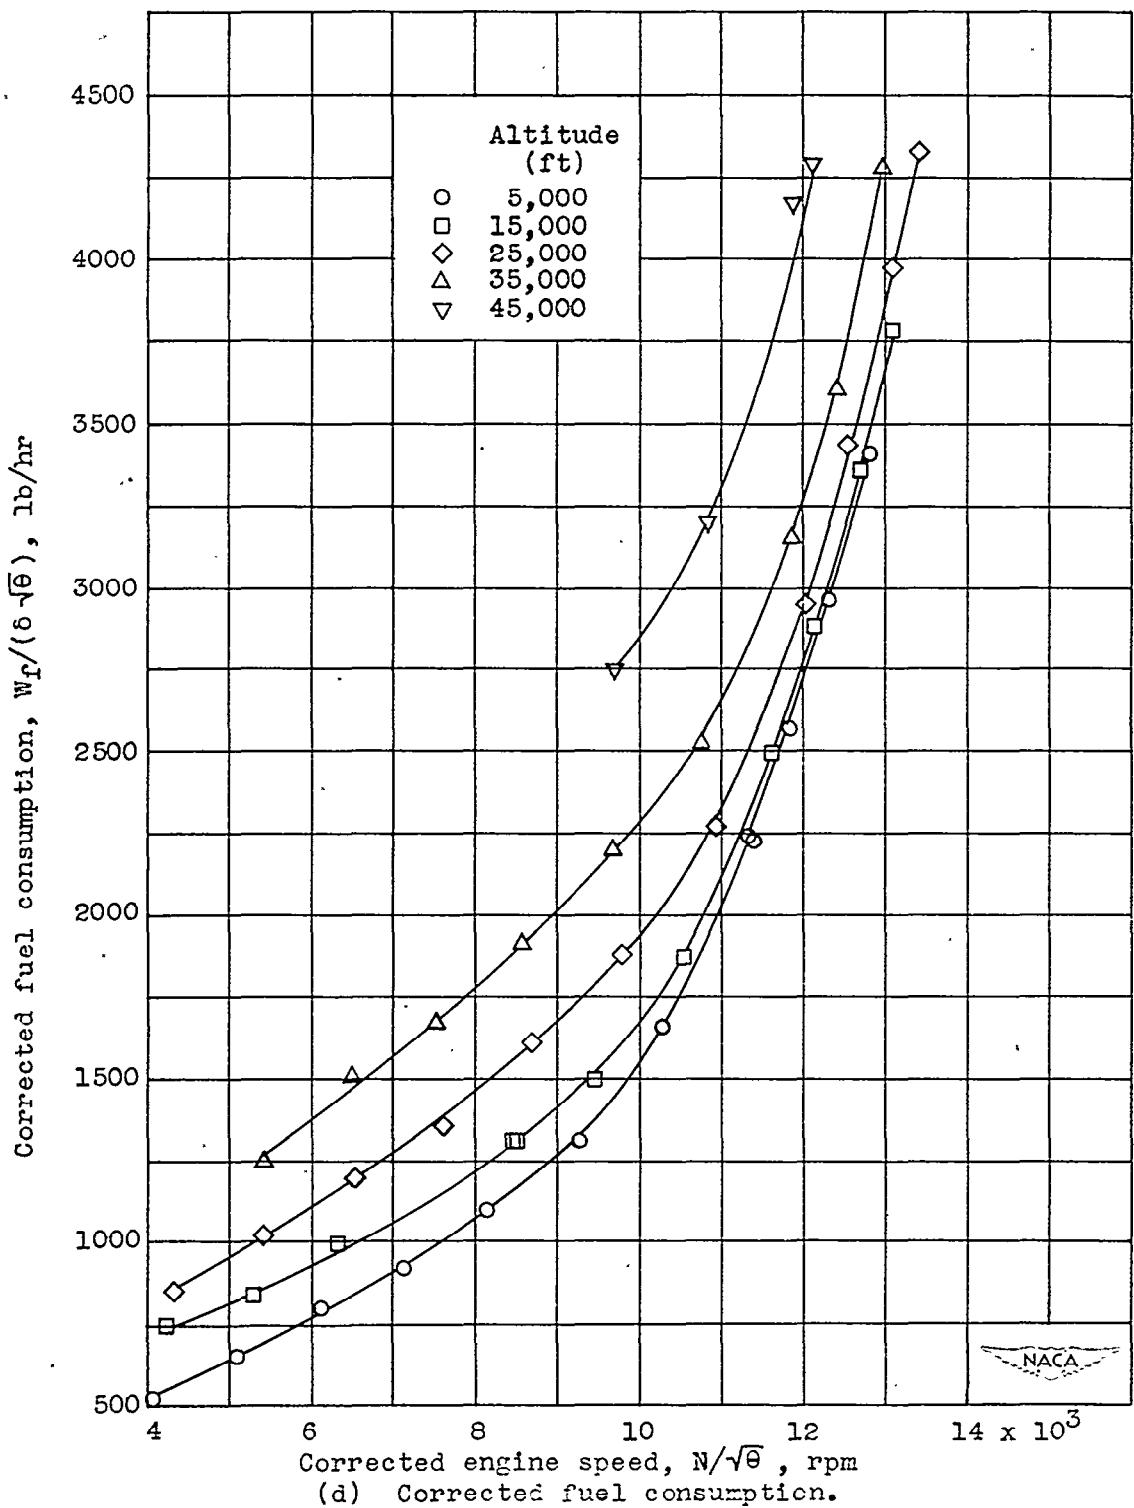

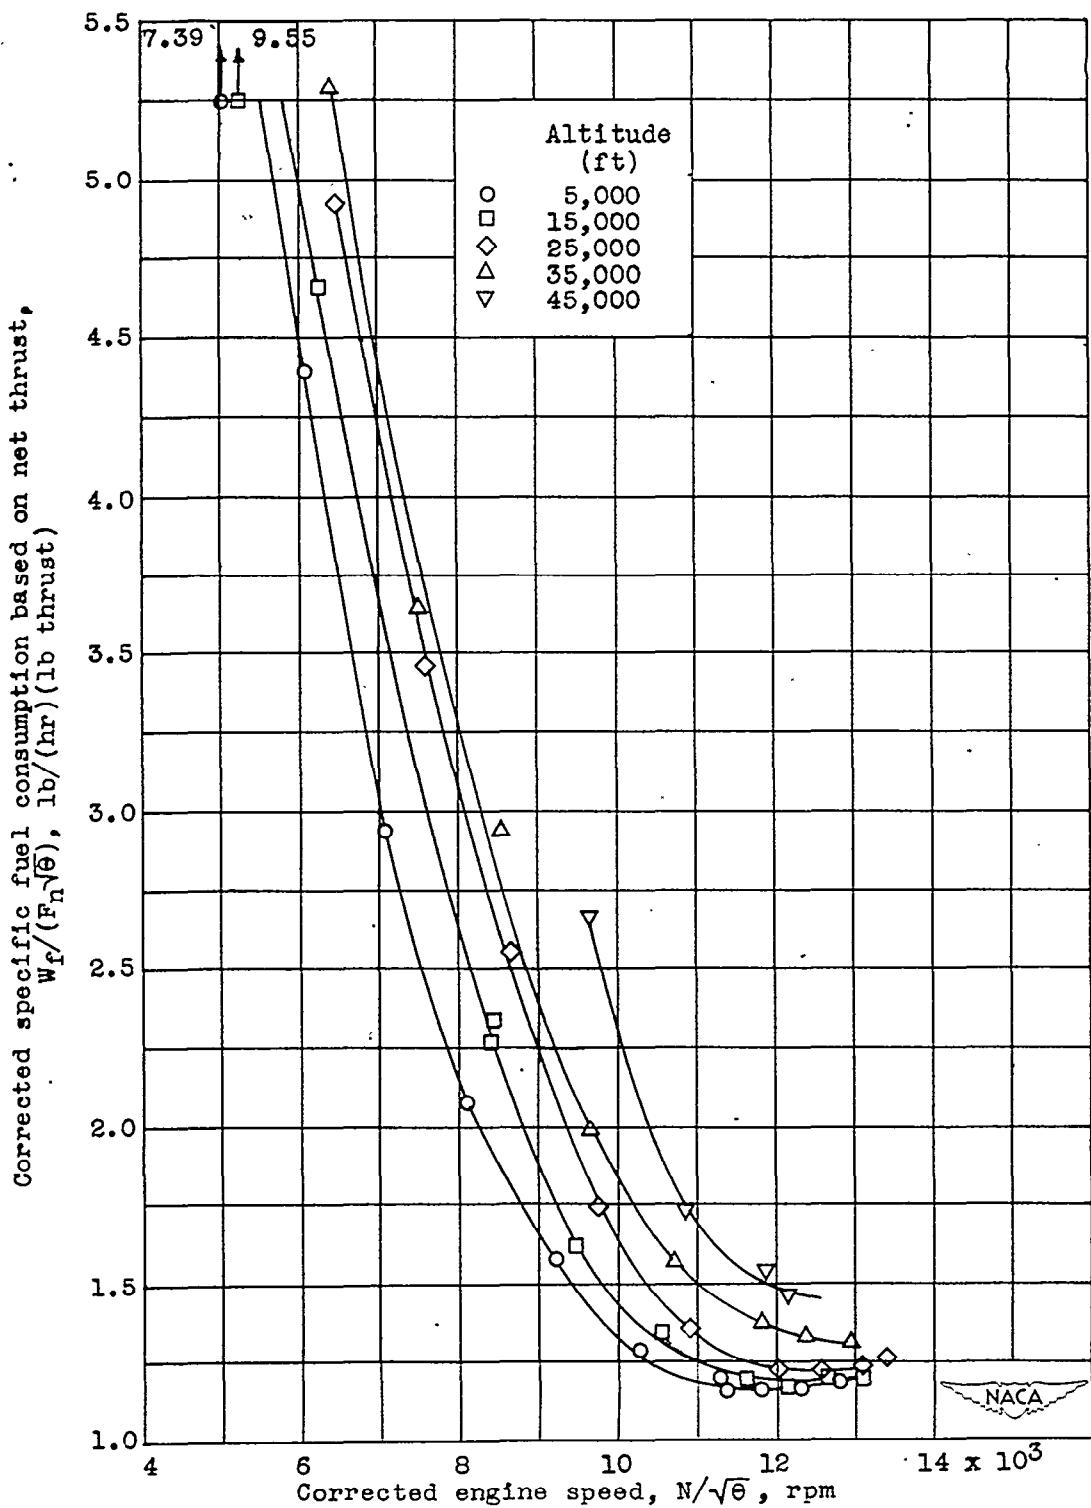

Figure 7. - Continued. Effect of altitude on variation of generalized turbojet engine performance with corrected engine speed. Flight Mach number, 0.25.

(e) Corrected specific fuel consumption based on net thrust.

Figure 7. - Continued. Effect of altitude on variation of generalized turbojet engine performance with corrected engine speed. Flight Mach number, 0.25.

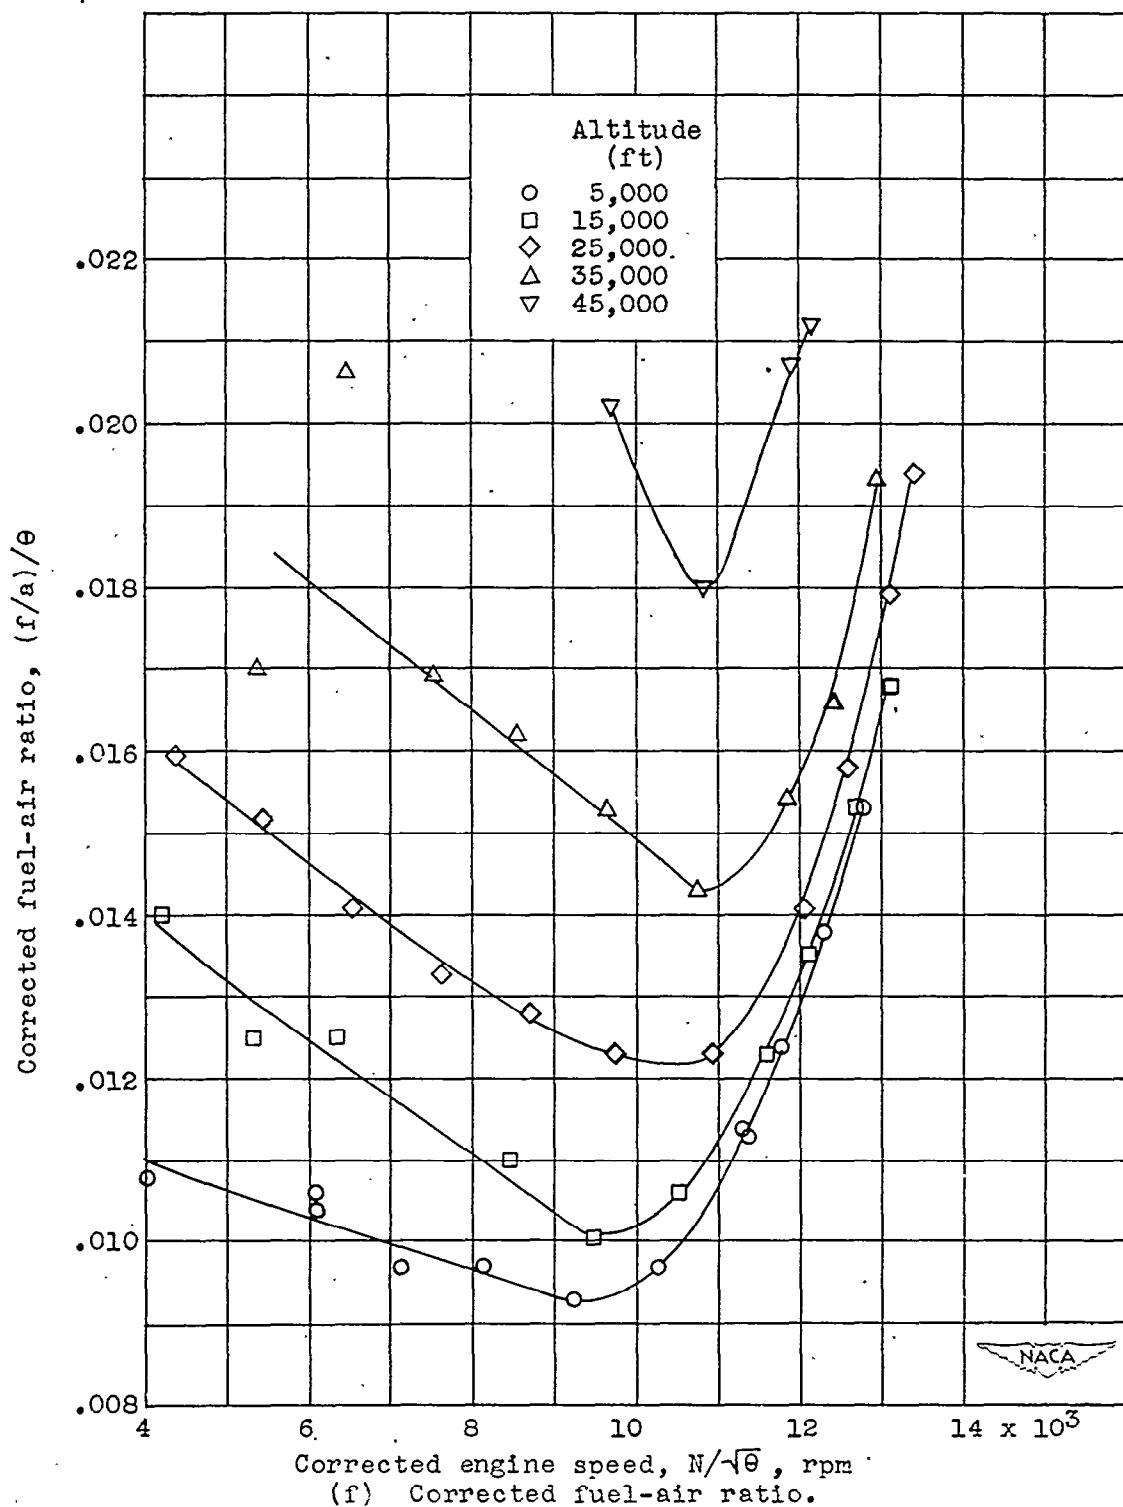

Figure 7. - Continued. Effect of altitude on variation of generalized turbojet engine performance with corrected engine speed. Flight Mach number, 0.25.

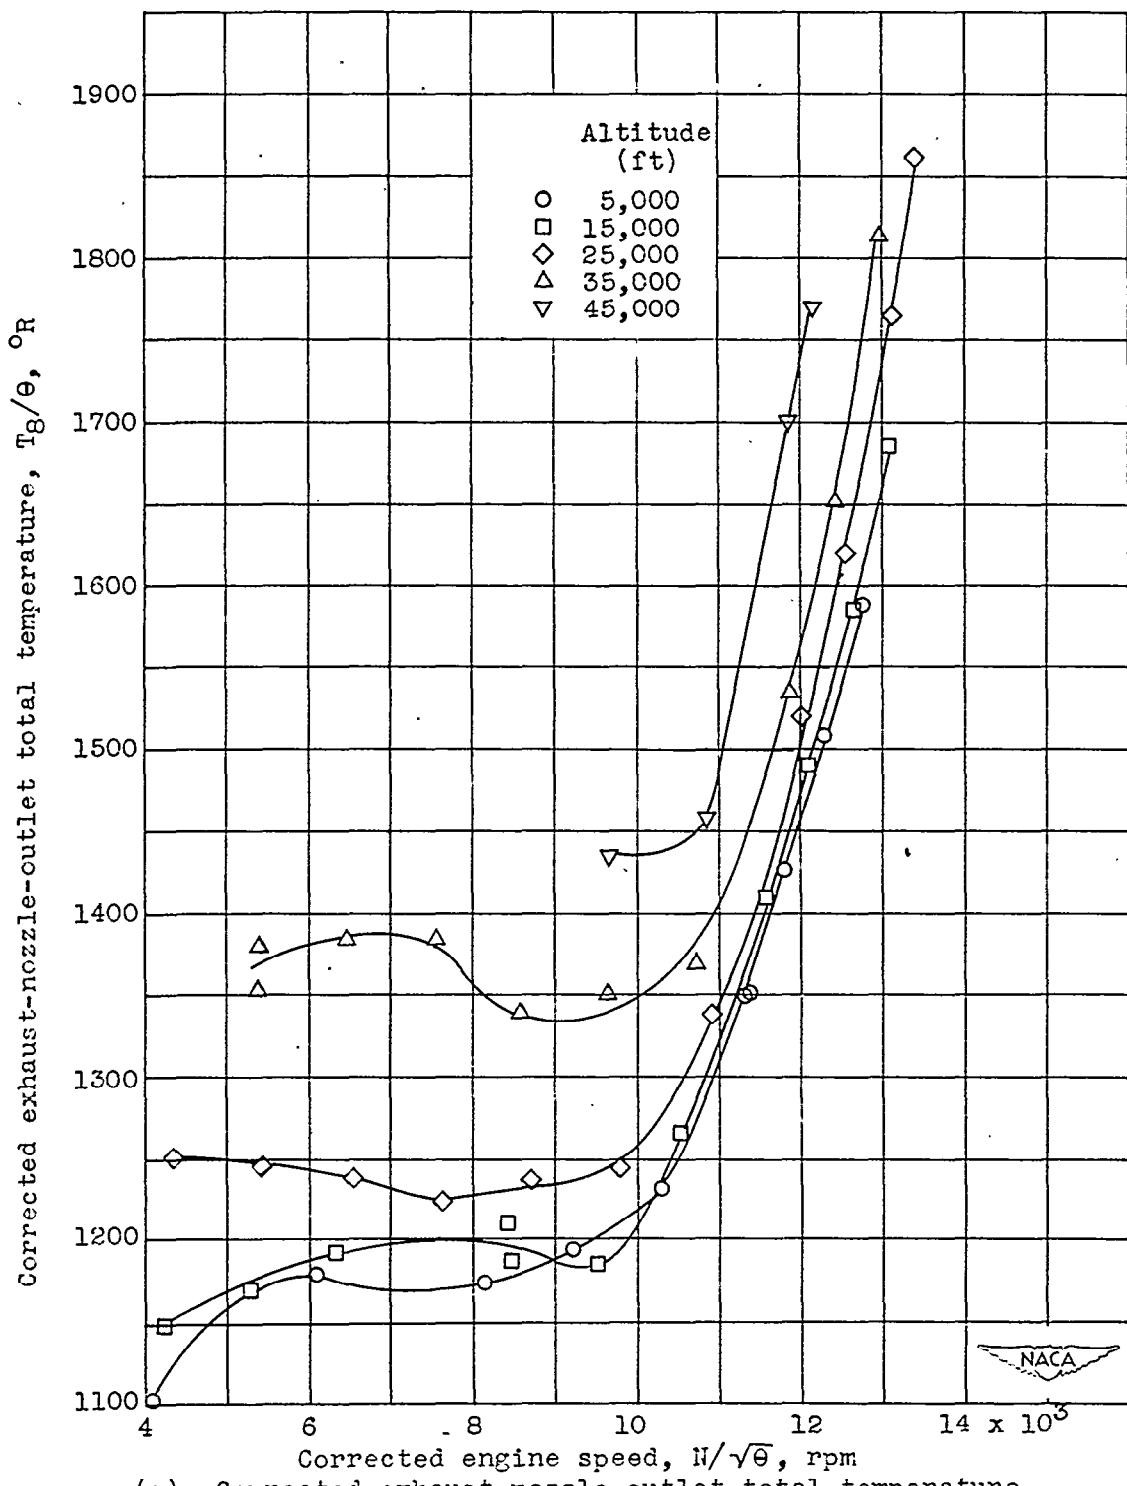

Figure 7. - Concluded. Effect of altitude on variation of generalized turbojet engine performance with corrected engine speed. Flight Mach number, 0.25.

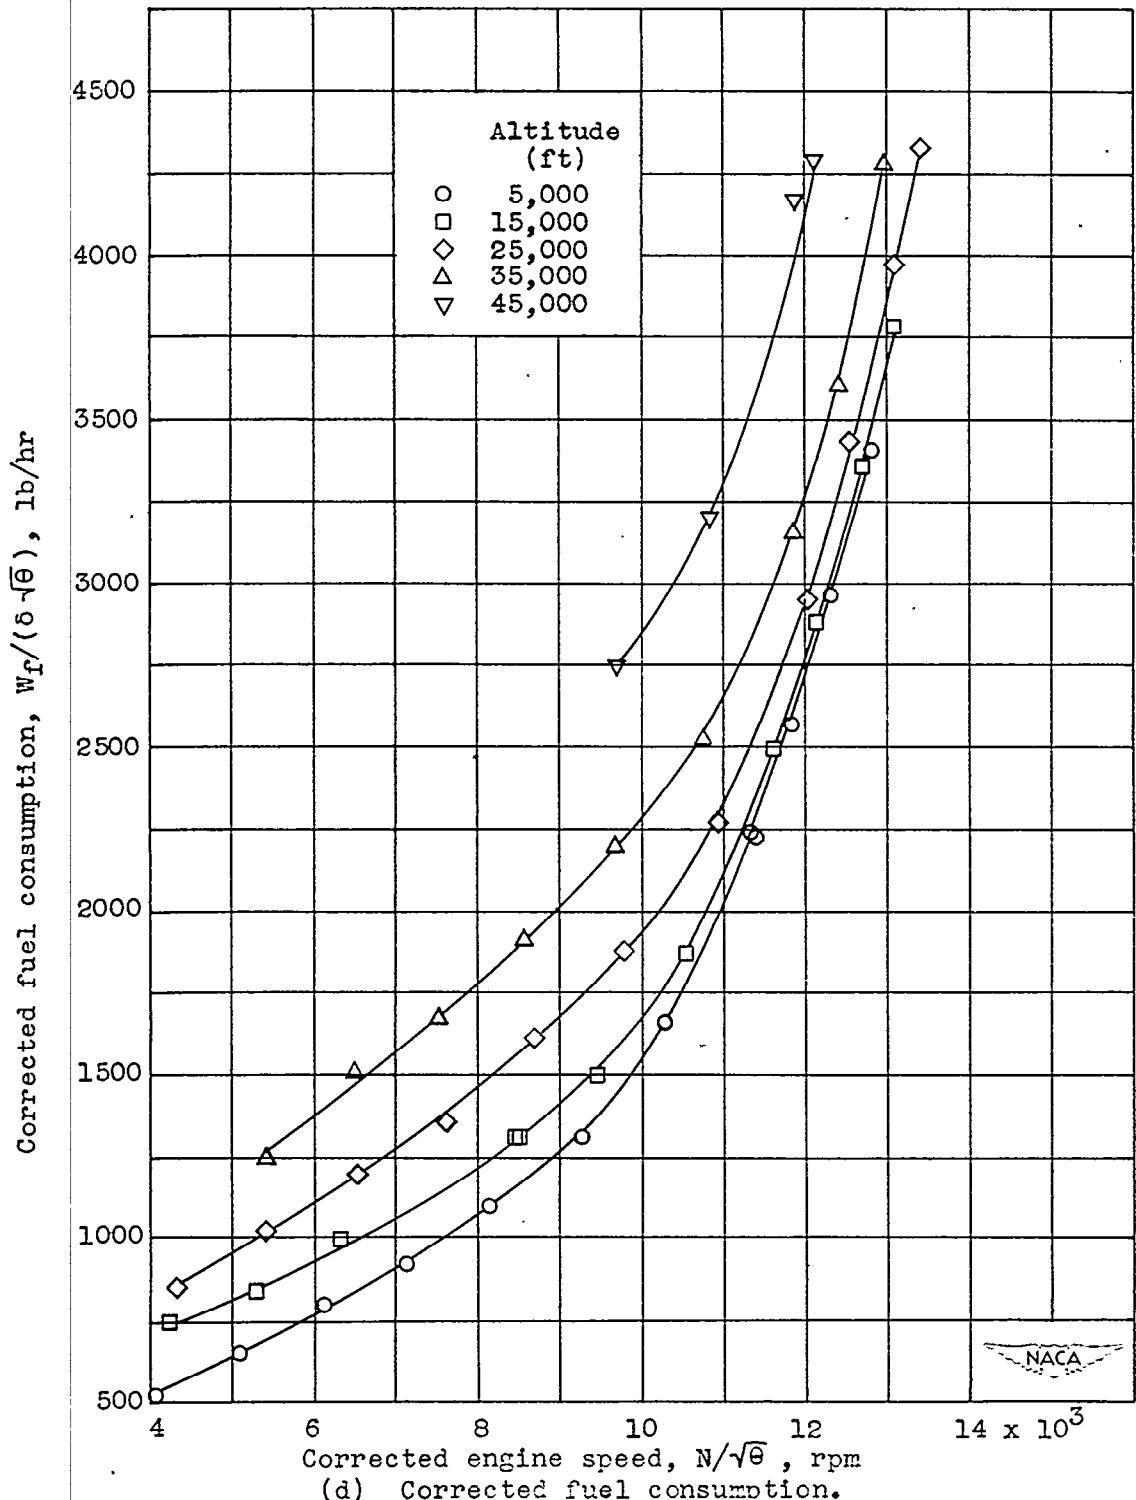

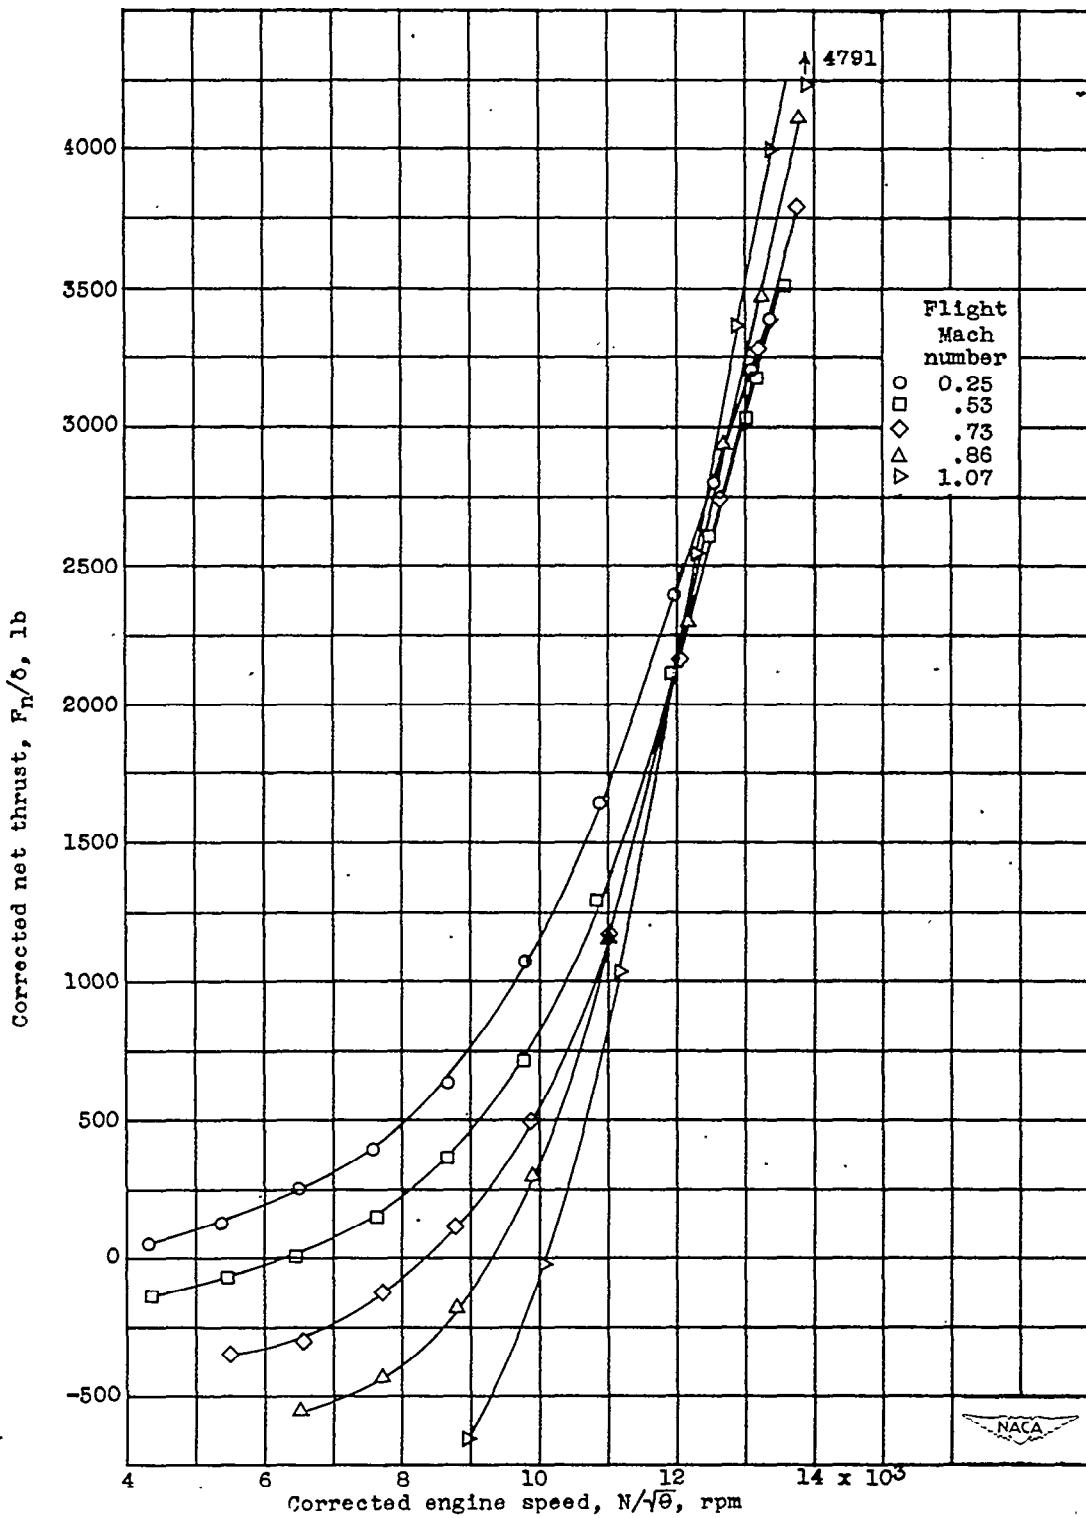

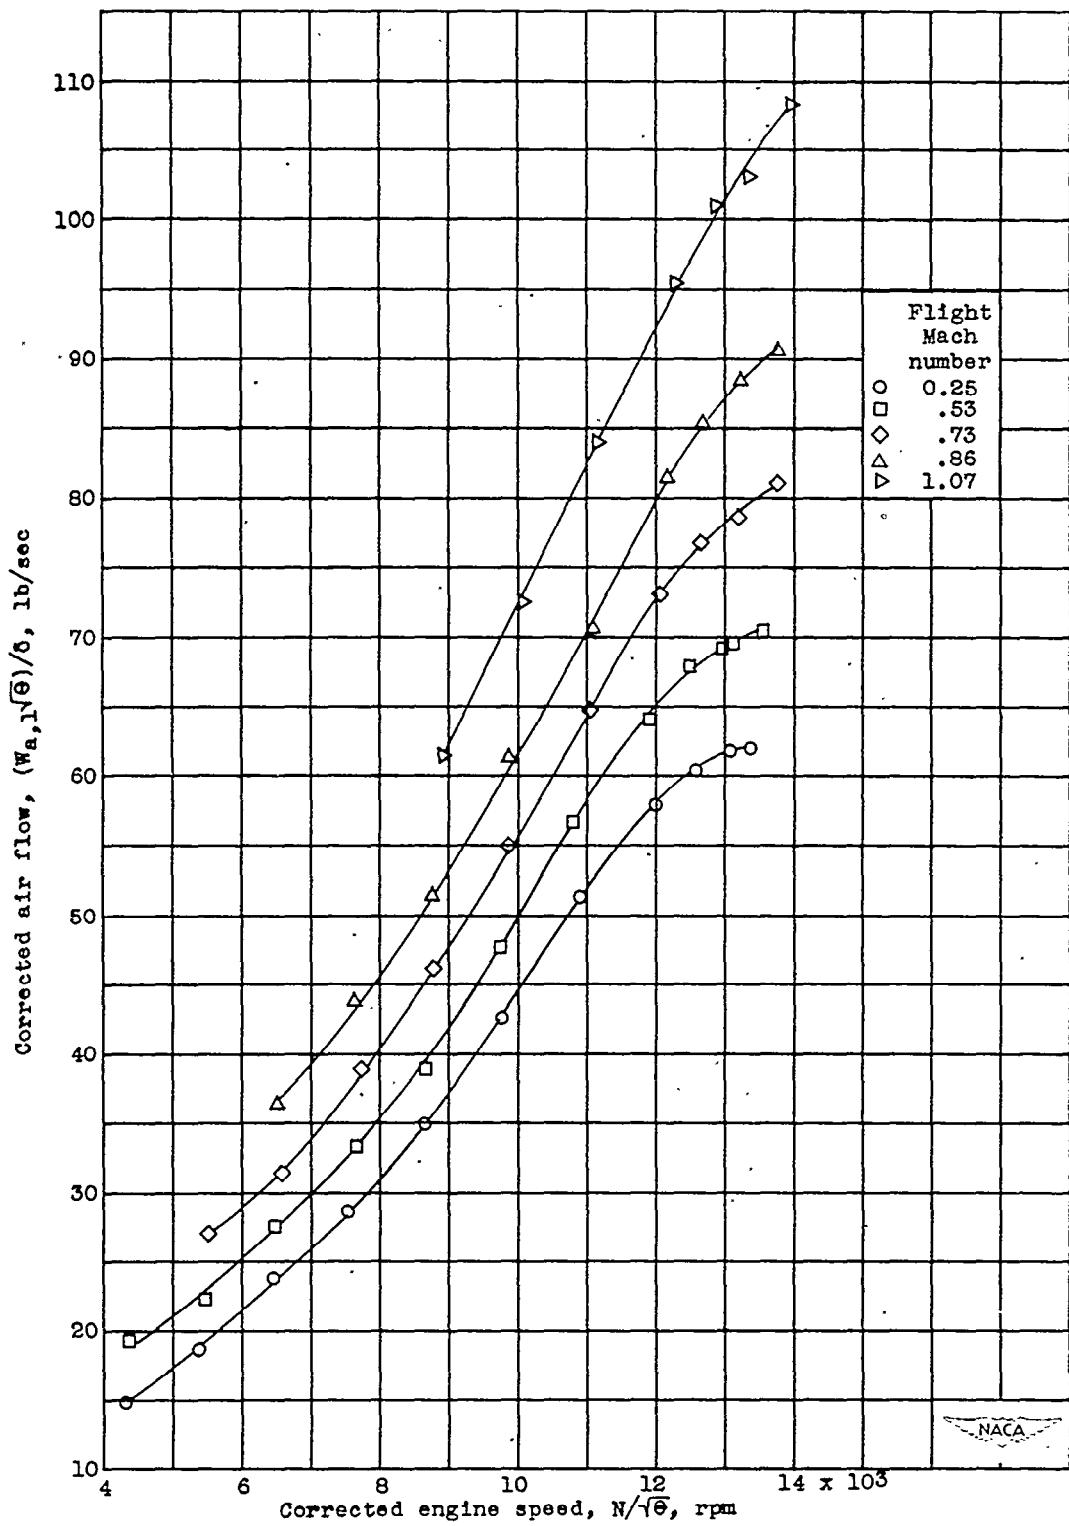

Figure 7. - Continued. Effect of altitude on variation of generalized turbojet engine performance with corrected engine speed. Flight Mach number, 0.25.

(b) Corrected net thrust.

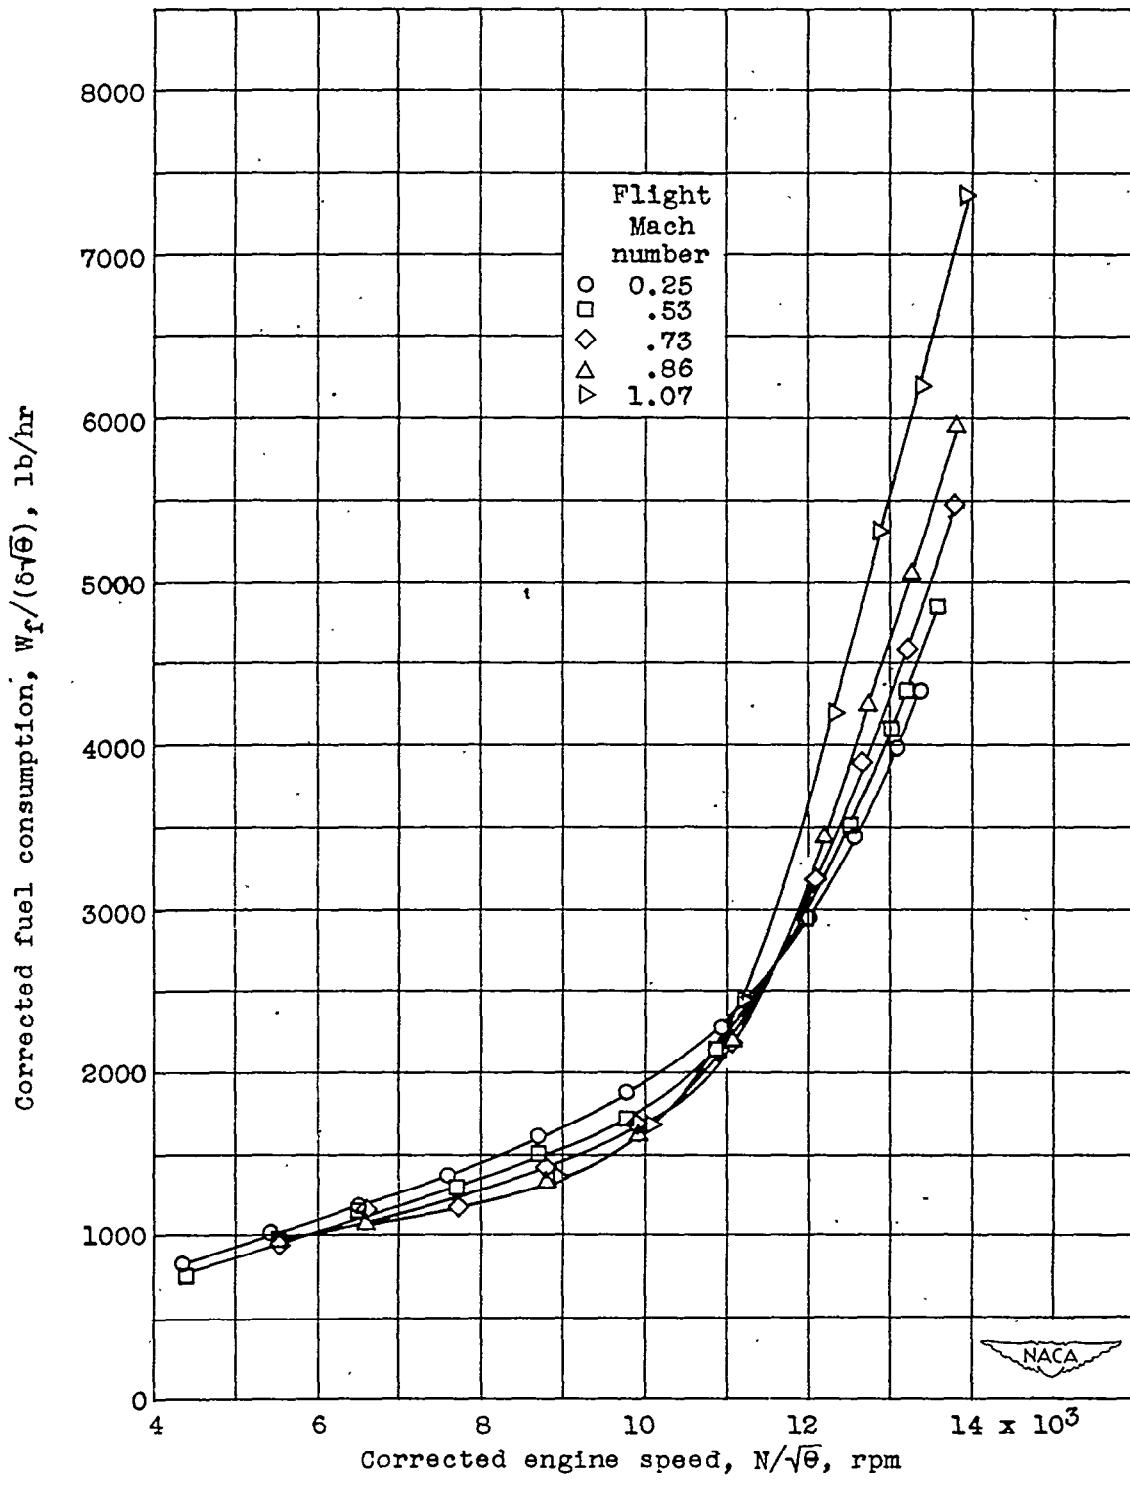

Figure 8. - Continued. Effect of flight Mach number on variation of generalized turbojet engine performance with corrected engine speed. Altitude, 25,000 feet.

(c) Corrected air flow.

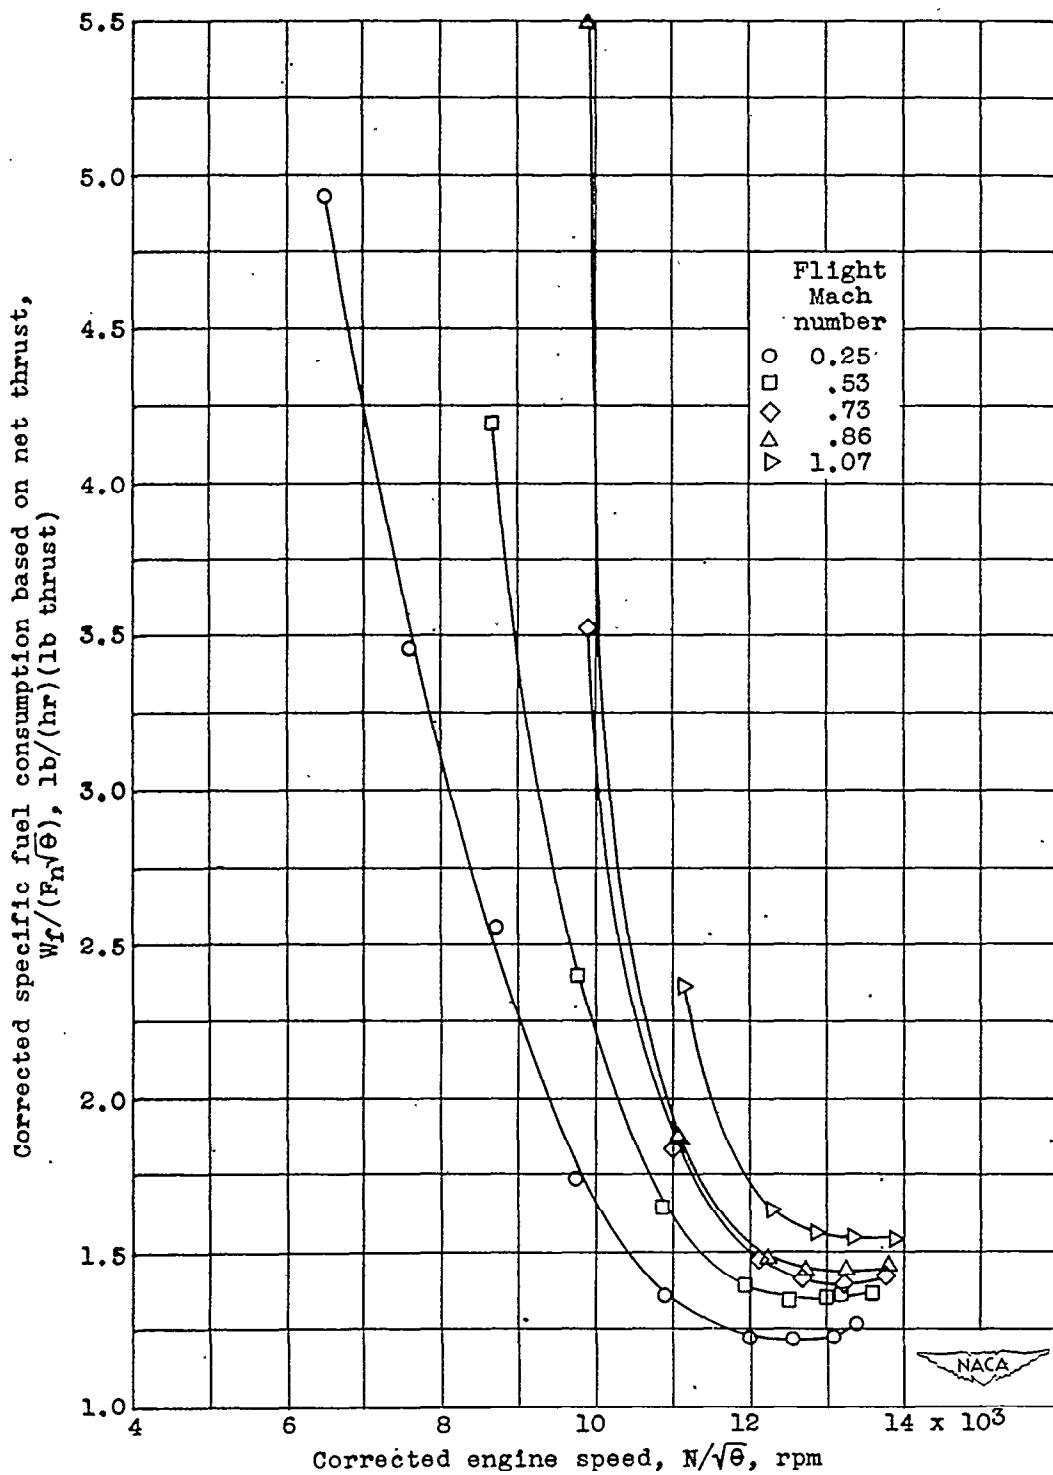

Figure 8. - Continued. Effect of flight Mach number on variation of generalized turbojet engine performance with corrected engine speed. Altitude, 25,000 feet.

CONFIDENTIAL

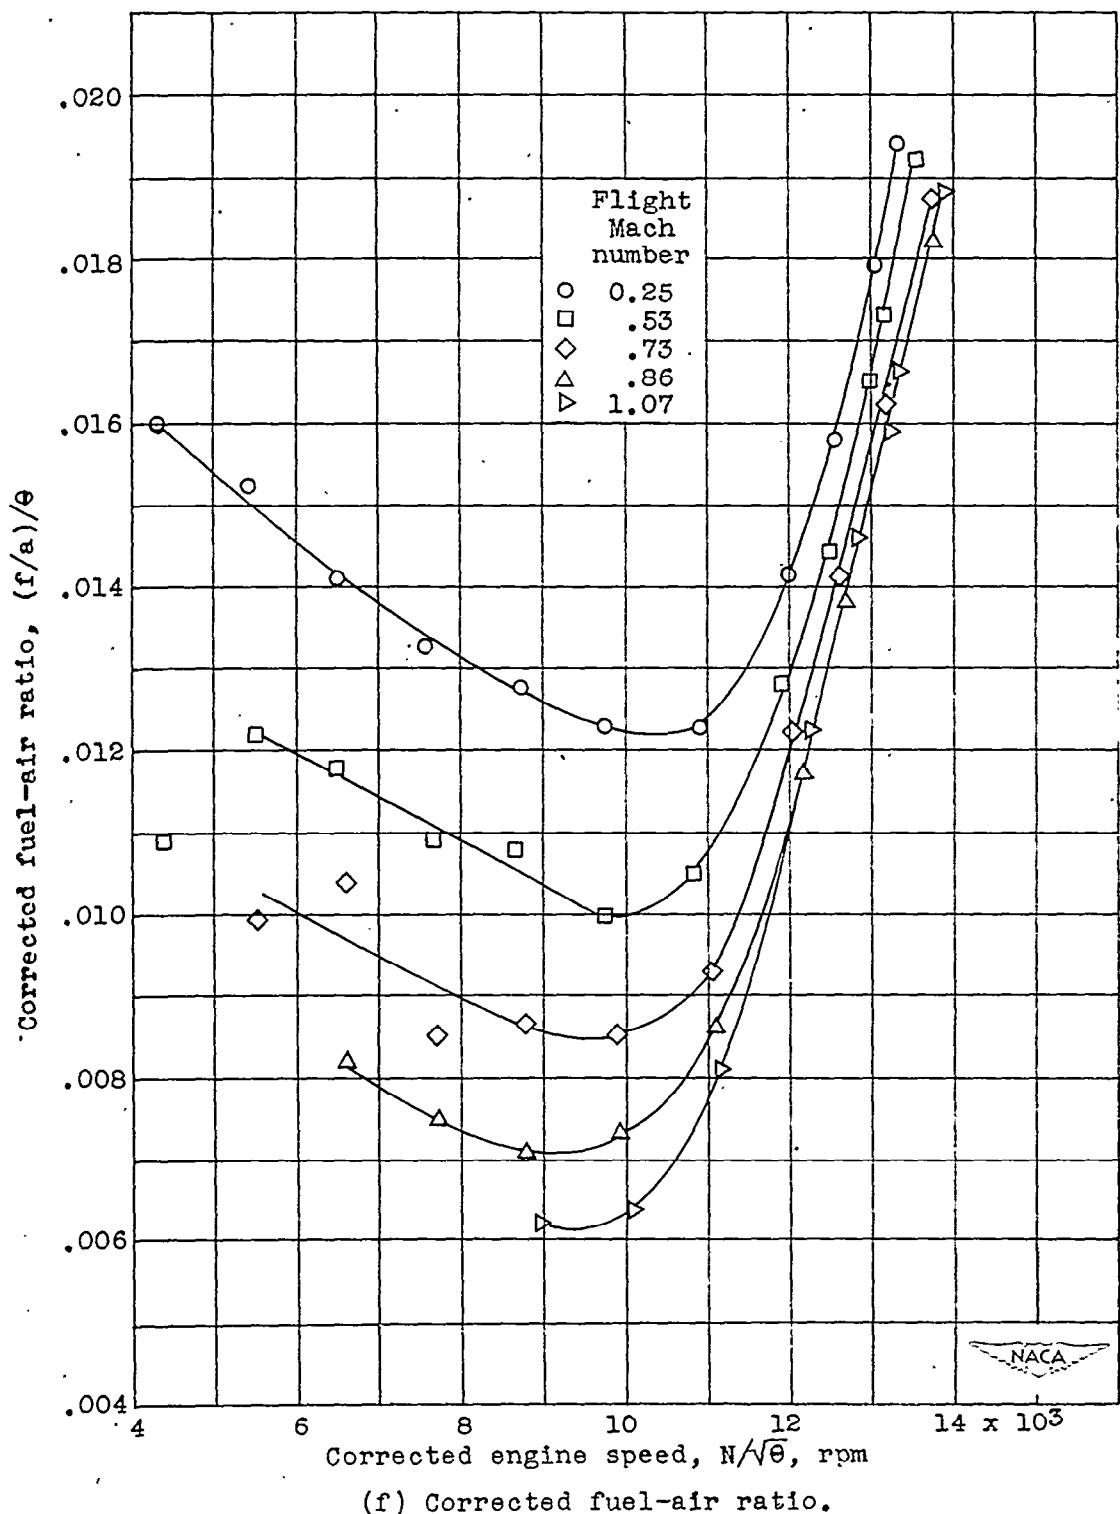

(d) Corrected fuel consumption.

Figure 8. - Continued. Effect of flight Mach number on variation of generalized turbojet engine performance with corrected engine speed. Altitude, 25,000 feet.

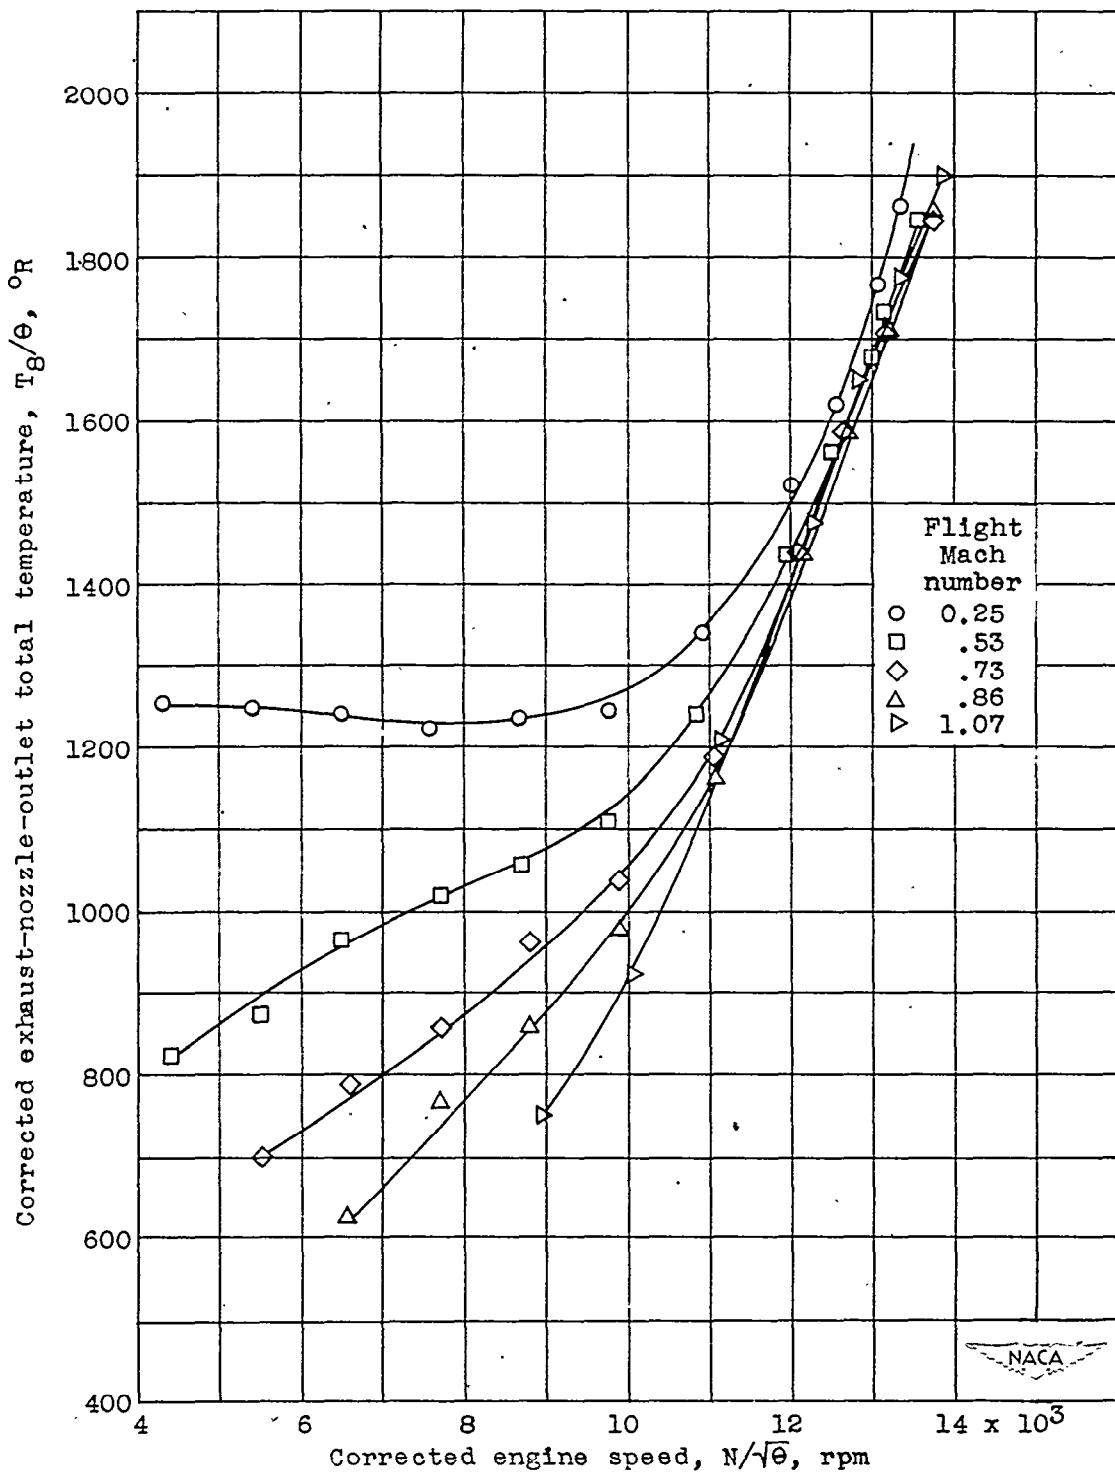

(e) Corrected specific fuel consumption based on net thrust.

Figure 8. - Continued. Effect of flight Mach number on variation of generalized turbojet engine performance with corrected engine speed. Altitude, 25,000 feet.

(f) Corrected fuel-air ratio.

Figure 8. - Continued. Effect of flight Mach number on variation of generalized turbojet engine performance with corrected engine speed. Altitude, 25,000 feet.

(g) Corrected exhaust-nozzle-outlet total temperature.

Figure 8. - Concluded. Effect of flight Mach number on variation of generalized turbojet engine performance with corrected engine speed. Altitude, 25,000 feet.
